This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

We couple a shell mesh on the surface of an embedded solid domain to its unfitted volumetric mesh.

The variationally consistent formulation depends only on displacement variables.

Its stabilization term triggers surface locking due to a polynomial mismatch between shell and solid elements.

Reduced quadrature of the stabilization term mitigates surface locking.

We present two use cases: patient-specific stress prediction in a vertebra and local rind buckling in a plant structure.
