Abstract

1 Openness is a multi-scale geomorphometric feature that has not been widely
 2 used despite its potential. The original approach, **which** averages zenith and
 3 nadir angles in the eight main compass directions, is modified to take into ac-
 4 count openness in all **available directions**; in addition, openness is calculated
 5 in different directions and different scales. A statistical analysis and Ran-
 6 dom Forest classification are carried out to check **whether** the modifications
 7 introduced provide significantly different results **from those of** the original
 8 approach. In addition, it was tested **whether** multi-scale and multi-direction
 9 openness provide relevant and complementary information to total openness.
 10 The results show that the original algorithm produces biased, **systematically**
 11 **higher, openness estimations**. In addition, multi-scale and multi-direction
 12 openness produce more accurate Random Forest classifications. Accuracy
 13 increases from 0.62 when using total openness to 0.66 when using the multi-
 14 scale approach, 0.73 when using **the** multi-direction approach and 0.75 when
 15 both are used.

Keywords: Geomorphometric Features, Openness, ANOVA, GRASS GIS
