9 Abstract

10

11 A model that has been widely applied to fractured rock comprises randomly distributed and oriented
12 plates. Formulae are given for the intersection statistics of infinite systems of such plates of mixed
13 shapes and sizes with lines, planes and each other; the results are expressed in terms of the number
14 density, n , and of the average area $\langle A \rangle$ and perimeter $\langle P \rangle$ of the plates. From Monte-Carlo studies it
15 has been found that a mixture of elliptical plates, each of area A and perimeter P , at the dimensionless
16 density $\rho = \langle A^k P^{3-2k} \rangle n$ with $k = 0.774$ is approximately invariant at the percolation threshold with
17 a critical value of about $\rho_c = 8.2 \pm 0.2$ for aspect ratios up to 16. The same result is found to apply to
18 any mixture of convex plate shapes and sizes provided that for each plate A and P are replaced by the
19 area and perimeter of an ellipse with the same aspect ratio and product AP . The results should be of
20 particular value in the interpretation of observed fracture statistics and in the construction of discrete
21 fracture network models.
