This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

Highlights

- numerically efficient solution to the problem of calculating electrostatic interactions between many dielectric particles is presented;
- the solution is general as it treats systems embedded in a homogeneous dielectric medium containing an arbitrary number of particles of any size, charge, dielectric constant and position in the three-dimensional space;
- the algorithmic complexity is reduced to linear scaling with respect to the number of particles;
- non-additivity of the electrostatic force in many-body systems is discussed;
- the effect of polarization at short separations on the total electrostatic force is considered for neutral – charged particle interactions, opposite charge and like charge interactions;
- the method is tested by the accurate estimations of the Madelung energy and constant of halite lattice;
- consequences for classical particle dynamics simulations are discussed.
