This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

Highlights

- Speech power is considered as an unique cue for binary mask estimation.
- The objective function used for convex optimization is effectively build by means of the cross-correlation between the power spectra of noisy speech and noise in each Gammatone channel.
- The gradient descent method is used to minimize the objective function with limited number of iteration.
- A decision factor for balancing the powers of noisy speech, the estimated speech and the pre-estimated noise is utilized to indicate the dominated components of speech or noise.
- Teager energy of the estimated speech and time-frequency unit smoothing are used to correct the local mask mistakes.
