Highlights:

- A kinetic model with three variables for chemical cleaning was established
- Good model prediction in total fouling resistance during chemical cleaning
- Potential engineering tool to optimize chemical cleaning conditions

Abstract:

In this study, a kinetic model was developed based on Hom–Haas model to describe the total membrane fouling resistance ($R_{tf}(t)$) during the chemical cleaning process of 0.1 μm PAN microfiltration (MF) membrane fouled with activated sludge suspension from submerged membrane bioreactors (SBR). The quantitative effects of different chemical cleaning conditions (temperature, TMP and stirring speed) on model parameters were determined. Results showed that the cleaning efficiency of
