This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

16 **ABSTRACT**

17 This study describes the sulfate-reducing (SR) and sulfide-oxidizing (SO) process
18 using Monod-type model with best-fit model parameters both being reported and
19 estimated. The molar ratio of oxygen to sulfide (R_{OS}) significantly affects the kinetics
20 of the SR+SO process. The S^0 is produced by SO step but is later consumed by
21 sulfur-reducing bacteria to lead to “rebound” in sulfide concentration. The model
22 correlated well all experimental data in the present SR+SO tests and the validity of
23 this approach was confirmed by independent sulfur bioreduction tests in four
24 denitrifying sulfide removal (DSR) systems. Modeling results confirm that the ratio of
25 oxygen to sulfide is a key factor for controlling S^0 formation and its bioreduction.
26 Overlooking S^0 bioreduction step would overestimate the yield of S^0 .

27 **Keywords:** Kinetic model; sulfur bioreduction; microaeration; data fitting

29 **1. INTRODUCTION**

30 Sulfate-bearing wastewaters are produced by pulp and paper manufacturers,
31 petrochemical plants, mineral processes and acid mine drainage from mining
32 activities (Knobel and Lewis, 2002). Under anaerobic environment with the presence
33 of chemical oxygen demand (COD), the sulfate-reducing bacteria (SRB) can convert
