Treatment Plant (WWTP). Currently the flows from different areas are usually determined by needs local to that area. During dry weather this may result in large variations in the flow into the WWTP. There are two reasons why this may be undesirable. Due to design peculiarities of some WWTP's this may disrupt the treatment process and necessitate the use of additional energy and chemicals. In other cases areas are connected to the same pressurized transport pipe line, so energy costs may be higher when multiple stations use the line at the same time. Due to the daily variation in the sewage flow from domestic and light industrial sources, limits on temporary in system storage and due to limitations on the range of discharges the pumps can deliver, minimizing the flow variations can be a complex problem. Under the assumption of a periodic inflow sufficient conditions for the existence of a solution are given. The conditions imply the existence of a repeatable pattern of a length less than a day. Abstract: In sewer systems sewage from different areas is often treated in a shared Waste Water imply the existence of a repeatable pattern of a length less than a day.

1. INTRODUCTION 1. INTRODUCTION 1. INTRODUCTION

In river deltas, polders and other areas with little natural relief, sewer systems are highly dependent on pumps for the transport of sewage over longer distances. For shorter distances (several city blocks), gravity drives the flow. Transport to a Waste Water Treatment Plant (WWTP) is usually by pressurized pipeline. More details on Dutch Transport to a Waste Water Treatment Plant (WWTP) Transport to a Waste Water Treatment Plant (WWTP) is usually by pressurized pipeline. More details on Dutch sewer systems can be found in NLingenieurs Sewer Systems Workgroup (2009). Often several areas with their own local sewer system at village or city district level share a WWTP. If they also share part of the pipeline to the $WWTP$ then it may save energy if we avoid running the WWTP then it may save energy if we avoid running the pumps at the same time. If the WWTP is sensitive to flow $\frac{1}{2}$ change then coordinating the running of the pumps will improve the efficiency of the WWTP. General information mprove the entrol of sewer systems can be found in Marinaki and Papageorgiou (2005); Ocampo-Martinez (2010); van Nooijen and Kolechkina (2013); Garc´ıa et al. (2015). Nooijen and Kolechkina (2013); Garc´ıa et al. (2015). Nooijen and Kolechkina (2013); Garc´ıa et al. (2015).

2. PRACTICAL PROBLEM STATEMENT 2. PRACTICAL PROBLEM STATEMENT 2. PRACTICAL PROBLEM STATEMENT 2. PRACTICAL PROBLEM STATEMENT

For a group of five large sewer systems that discharge to the same WWTP very large inflow variations under dry weather circumstances were disrupting the biological processes at the WWTP. The responsible organizations decided to investigate the possibility of reducing those processes at the WWTP. The responsible organizations processes at the WWTP. The responsible organizations decided to investigate the possibility of reducing those variations. Limits on local storage, variation in the inflow into the sewer system over the day and limits on realizable not discuss the system over the day and innue on redinational pump flows make the problem non-trivial. This paper not discuss the design of a practical control system for this problem. It will deal only with establishing sufficient conditions for a solution to the coordination problem to conditions for a solution to the coordination problem to conditions for a solution to the coordination problem to For a group of five large sewer systems that discharge exist within the constraints imposed. The importance of this demonstration lies in the fact that, depending on the and demonstration nos in the fact that, depending on the specific constraints, the problem itself may very well either unsolvable or NP complete. unsolvable or NP complete. unsolvable or NP complete. $T_{\rm H}$ show the problem may be $T_{\rm H}$ complete.

To show the problem may be NP complete we reduce a version of it to a multiple subset sum problem. Suppose we have m pumps that have a fixed capacity q_i that can be either on or off. Moreover, we have a fixed time step Δt and we can store n time steps worth of (stepwise constant) inflow $q_{\text{in},i}$ in each system. Finally, suppose that for all $i = 1, 2, \ldots, m$ we have $\sum_{i=1}^{n}$

$$
n_i = \frac{\sum_{k=1}^{n} q_{\text{in},i}(k)}{q_i} \in \mathbb{N}
$$
 (1)

with $n_i < n$. Now define with nice and nice and nice with $n_i < n$. Now define

with
$$
n_i < n
$$
. Now define\n
$$
q_{\text{tgt}} = \frac{1}{mn} \sum_{i=1}^{m} \sum_{k=1}^{n} q_{\text{in},i}(k) \tag{2}
$$

To obtain an an outflow that discharges all inflow we need to find $x_{ik} \in \{0, 1\}, i = 1, 2, ..., m, k = 1, 2, ..., n$ such that we that we that we that we $\frac{m}{m}$ $\frac{n}{n}$ $\sum_{n=1}^{\infty}$

maximize
$$
\sum_{i=1}^{m} \sum_{k=1}^{n} q_i x_{ij}
$$
 (3)

subject to subject to subject to

$$
\sum_{i=1}^{m} q_i x_{ik} \le q_{\text{tgt}}, \, k = 1, 2, \dots, n \tag{4}
$$

3. ABSTRACT PROBLEM STATEMENT

3.1 General statement

We have m pairs (V_i, Q_i) , $i = 1, 2, \ldots, m$ where V_i is a closed, bounded, non-negative interval in R that represents the lower and upper bounds on the volume of sewage that can be stored in sewer system i and Q_i is a closed, bounded, non-negative interval in R that represents the lower and upper bounds on the range of flows that the pumping station for sewer system i can generate. Each pumping station will either be off or be generating a flow in Q_i . Each system has an inflow given by a non-negative integrable function $q_{\text{in},i}$. We are looking for a set of nonnegative integrable functions q_i , together with a set of starting volumes $v_{0,i}$ such that for all $t \geq 0$

and

$$
\begin{array}{c}\n t \\
\uparrow \\
t\n \end{array}
$$

 $q_i (t) \in \{0\} \cup Q_i$ (6)

$$
v(t) = v_{0,i} + \int_{\tau=0}^{t} q_{\text{in},i}(\tau) - q_i(\tau) d\tau \in V_i \tag{7}
$$

such that the variation over time of the inflow to the WWTP,

$$
q_{\rm wwtp}(t) = \sum_{i=1}^{m} q_i(t)
$$
\n(8)

is minimal.

3.2 Simplified problem

We assume that the inflows are periodic with period $T_{\rm p}$ and that the solution should result in a constant inflow into the WWTP, from mass conservation it follows that in that case we must have

$$
q_{\rm wwtp} = \frac{1}{T_{\rm p}} \int_{\tau=0}^{T_{\rm p}} \sum_{i=1}^{m} q_{\rm in, i}(\tau) d\tau
$$
 (9)

4. CONDITIONS FOR EXISTENCE OF A SOLUTION

4.1 Road map

We will start by deriving conditions that are sufficient for a solution to exist when $\inf Q_i = 0$ for all i. Next we derive conditions that show we can keep the separate districts within the allowed volume range in case inf $Q_i > 0$. We will then show that the simplified problem reduces to a problem of optimal use of a rectangular piece of material to create constrained smaller rectangles. Finally some conditions will be given that guarantee existence of a solution of the simplified problem.

4.2 Basic assumptions

and that

We are considering only dry weather circumstances. During heavy precipitation events other rules apply. The design of sewer systems is almost always such that the installed pumping capacity exceeds the maximum dry weather flow. We will therefore assume that q_{in} is bounded

$$
\|q_{\text{in},i}\|_{\infty} < \infty \tag{10}
$$

$$
\|q_{\text{in},i}\|_{\infty} < \sup Q_i \tag{11}
$$

Usually, the pumping stations are designed for local operation, the pump starts when a certain water level in the wet well is exceeded and pump stops when the level drops below a second, lower levels. In other words, we may assume that there is sufficient local storage to run the pumps a reasonable time.

4.3 Existence of a solution with zero lower bound on pump capacity

A necessary condition for the existence of a solution is that the equivalent one district case, with volume

$$
V_{\text{total}} = \sum_{i=1}^{m} V_i(t) \tag{12}
$$

and flow range

$$
Q_{\text{total}} = \sum_{i=1}^{m} Q_i(t) \tag{13}
$$

should have a solution. Here addition is interval addition. The following lemma provides a condition for the existence of a solution for the one district case that is verifiable by computer.

Lemma 1. Given a pair (V, Q) , a starting volume interval V_0 , a bounded periodic inflow q_{in} with period T_{p} and a time step Δt such that $n = T_{\rm p}/\Delta t$ is a positive integer, if

$$
\bar{q} = \frac{1}{T_{\rm p}} \int\limits_{\tau=0}^{T_{\rm p}} q_{\rm in}(\tau) d\tau \in Q \tag{14}
$$

 $\|q_{\text{in}}\|_{\infty} < \sup Q$ (15)

$$
f_{\rm{max}}
$$

and

$$
V_0 + \int\limits_{\tau=0}^{\kappa\Delta t} (q_{\rm in}(\tau) - \bar{q}) d\tau \subseteq \qquad (16)
$$

 $[\inf V + \Delta t \sup Q, \sup V - \Delta t \sup Q]$ for $k = 0, 1, 2, \ldots, n$ then a constant outflow

 k^{λ}

$$
q\left(t\right) = \bar{q}_{\text{in}}\tag{17}
$$

will keep the stored volume between the bounds specified by V .

Proof.

The condition implies that the volume will be within the bounds $[\inf V + \Delta t \sup Q, \sup V - \Delta t \sup Q]$ at the end of a time step. The boundedness of q_{in} (Equation 15) together with the periodicity of the inflow places the solution in V for all t .

Next we consider multiple districts.

 $Lemma 2. If we have m districts and there is a constant.$ flow solution for the separate districts then there is a solution such that the sum of the flows is constant and equal to q_{wwtp} as defined in Equation 9.

Proof.

This follows immediately from the definitions.

4.4 Existence of a solution with a non-zero lower bound on pump capacity

If there is a solution for a district with the outflow equal to the mean inflow but the mean inflow is lower than inf Q Download English Version:
