*Keywords:* NH3–SCR NO Ce–Mo–Ti mixed oxide Homogeneous precipitation

#### a b s t r a c t

A series of Ce–Mo–Ti mixed oxide catalysts prepared by a homogeneous precipitation method were evaluated for selective catalytic reduction (SCR) of NO with NH<sub>3</sub>. These catalysts were characterized by BET, XRD, XPS, SEM, TEM and H2-TPR. The experimental results indicated that the optimal Ce–Mo–Ti mixed oxide catalyst (Ce<sub>40</sub>Mo<sub>10</sub>Ti) exhibited excellent SCR activity in a wide temperature range of 250–450 °C as well as strong resistance to high gas hourly space velocity,  $10\%$  H<sub>2</sub>O or/and  $1000$  ppm SO<sub>2</sub>. The introduction of Mo could enhance redox property and increase the amount of  $Ce^{3+}$ , accompanied by the increment of oxygen vacancies and adsorbed oxygen species on the catalyst surface, which were advantageous to the SCR reaction over Ce–Mo–Ti oxide catalyst. In addition, good dispersion of Ce and Mo species on TiO<sub>2</sub> and their synergetic interaction also contributed to its remarkable NH<sub>3</sub>–SCR performance.

#### **1. Introduction**

Selective catalytic reduction (SCR) of NO with  $NH<sub>3</sub>$  has been regarded as one of state-of-the-art technologies for the control of  $NO<sub>x</sub>$  emissions from stationary sources.  $V<sub>2</sub>O<sub>5</sub>$ -WO<sub>3</sub>(or MoO<sub>3</sub>)/TiO<sub>2</sub> has been extensively utilized for the past few decades. Great attention is paid nowadays to environment-friendly vanadium-free catalysts for SCR applications mainly due to several inevitable drawbacks of vanadium-based catalysts, including biological toxicity of  $V_2O_5$ , relatively narrow activity temperature window (300–400 °C), high oxidation of  $SO_2$  to  $SO_3$  with increasing  $V_2O_5$ loadings [\[1\]](#page--1-0) and drop in  $N_2$  selectivity at high temperatures [\[2\].](#page--1-0) Among possible substitutes, cerium-based oxides are of considerably practical concern because of the remarkable oxygen storage/release capability and redox property of  $CeO<sub>2</sub>$  [\[3\].](#page--1-0) Varieties of cerium-based oxide catalysts have been reported, such as Ce–Ti [\[4–6\],](#page--1-0) Ce–W–Ti [\[7–9\],](#page--1-0) Ce–Nb [\[10\],](#page--1-0) Ce–P [\[11\],](#page--1-0) etc.

 $MoO<sub>3</sub>$  has been used as a structural and chemical promoter in commercial vanadia-based catalysts [\[3\].](#page--1-0) In recent years, Liu et al.  $[12]$  and our group  $[13]$  added Mo to  $CeO<sub>2</sub>/TiO<sub>2</sub>$  catalyst by an impregnation and single step sol–gel, respectively. Both of them showed good catalytic activity and certain resistance to  $H_2O$

and  $SO_2$ . It is well established that the activity of a catalyst is highly dependent on its preparation method in most cases [\[14\].](#page--1-0) Homogeneous precipitation has been demonstrated to contribute to improving the dispersion and prevent the aggregation of metal oxide species at high content, which will be beneficial to provide more active sites [\[15\].](#page--1-0) This is crucial to the enhancement of the catalytic performance over mixed metal oxide catalysts. It was reported that mixed oxides of Ce–Ti [\[5\],](#page--1-0) Ce–W–Ti [\[8\],](#page--1-0) Ce–W [\[16\],](#page--1-0) Co–Al  $[17]$  and V–Ce  $[18]$ , prepared by a homogeneous precipitation method, showed superior SCR performances. However, to our best knowledge, there have been few reports on Ce–Mo–Ti oxide catalyst prepared by a homogeneous precipitation method for the SCR of NO with  $NH<sub>3</sub>$  until our present study.

In this work, a homogeneous precipitation method was employed to prepare Ce–Mo–Ti mixed oxide for the SCR of NO with NH<sub>3</sub>. The catalysts were characterized by BET and pore size distribution measurements, XRD, XPS, SEM, TEM and  $H_2$ -TPR measurements.

#### **2. Experimental**

#### *2.1. Catalysts preparation*

Ce–Ti, Mo–Ti and Ce–Mo–Ti mixed oxides were synthesized by a homogeneous precipitation method. Cerium nitrate  $(Ce(NO_3)_3.6H_2O)$ , titanium sulfate  $(Ti(SO_4)_2)$  and ammonium

**Table 1** Composition of  $Ce_{40}Ti$  and  $Ce_{40}Mo_{10}Ti$ .

Samples	Element concentrations (wt.%)		
	۲e	Mo	Ti
Ce <sub>40</sub> Ti	22.19		34.76
Ce <sub>40</sub> Mo <sub>10</sub> Ti	20.59	3.83	32.29

molybdate  $((NH_4)_6Mo_7O_{24}\cdot 4H_2O)$  were used as the precursors of Ce, Ti and Mo. The required amounts of precursors were added to 500 mL deionized water. Superfluous urea (35 g) was then mixed into the above solution, followed by continuously magnetic stirring at 90 °C for 8 h. The deposits were filtered and thoroughly washed with deionized water until the filtrate was neutral. The resulted precipitates were dried at 100 °C overnight and subsequently calcined at  $400^{\circ}$ C in the air for 4h. The obtained particles were pressed, milled and sieved out for further studies. The catalysts were denoted as  $Ce<sub>m</sub>Mo<sub>n</sub>Ti$ , in which *m* and *n* represented the weight loadings of  $CeO<sub>2</sub>$  and  $MoO<sub>3</sub>$  in 100 g TiO<sub>2</sub>, respectively. For example, in the case of  $Ce_{40}Mo_{10}Ti$ , the weight ratio of  $CeO<sub>2</sub>/MoO<sub>3</sub>/TiO<sub>2</sub>$  was 40:10:100 and the corresponding weight ratio of their precursors was about 101:12:300. The stoichiometries of Ce<sub>40</sub>Ti and Ce<sub>40</sub>Mo<sub>10</sub>Ti were confirmed by using an inductively coupled plasma atomic emission spectroscopy (ICP-AES) and the results are shown in Table 1.

#### *2.2. Catalytic activity measurements*

The catalytic activity measurements were carried out in a continuous-flow fixed-bed quartz reactor with required amounts of catalysts (60–100 mesh). The feed gas contained 1000 ppm NO, 1000 ppm NH<sub>3</sub>, 3 vol.% O<sub>2</sub>, 10 vol.% H<sub>2</sub>O (when used), 1000 ppm  $SO<sub>2</sub>$  (when used) and balance N<sub>2</sub>. The concentrations of the products, including NO,  $NO<sub>2</sub>$ , SO<sub>2</sub> and O<sub>2</sub>, were collected by the gas analyzer (350 Pro, Testo). The steady-state activity data were recorded after about 30 min at each temperature.

#### *2.3. Characterization of catalysts*

BET analysis of the catalysts was determined from  $N_2$  adsorption/desorption at 77 K using an automated gas sorption system (Micromeritics ASAP 2020).

X-ray diffraction (XRD) patterns were recorded on an X'Pert PRO MPD system (PANalytical Corp.) with Cu K $\alpha$  radiation  $(\lambda = 0.15406$  nm).

X-ray photoelectron spectroscopy (XPS) measurements were carried out with a Thermo ESCALAB 250 spectrometer equipped with an X-ray source with Al K $\alpha$  radiation (1486.6 eV). The observed spectra of Ce 3d, Mo 3d, Ti 2p and O 1s were calibrated using C 1s peak ( $BE = 284.6$  eV) as standard.

The scanning electron microscopic (SEM) images were graphed with a Helios NanoLab 600i Dual Beam System (FEI Company) and the transmission electron microscopic (TEM) images were performed on a JEM-2010 microscope (JEOL Company).

The hydrogen temperature-programmed reduction experiments  $(H<sub>2</sub>-TPR)$  were measured on FINESORB-3010 chemisorption analyzer (FINETEC Instruments Corp.) with 0.1 g of the catalysts with a thermal conductivity detector (TCD).

#### **3. Results and discussion**

#### *3.1. NH3–SCR activity*

#### *3.1.1. Effect of CeO2 loadings*

To find the optimal  $CeO<sub>2</sub>$  loading, Mo $O<sub>3</sub>$  loading was kept at 10 wt.% TiO<sub>2</sub>. Fig. 1 shows the NO conversions as a fuction of reac-

**Fig. 1.** NH<sub>3</sub>–SCR activities over various catalysts with different CeO<sub>2</sub> loadings. Reaction conditions:  $[NO] = [NH<sub>3</sub>] = 1000$  ppm,  $[O<sub>2</sub>] = 3$  vol.%, balance N<sub>2</sub> and  $GHSV = 90,000 h^{-1}$ 

**Fig. 2.** NH<sub>3</sub>-SCR activities over various catalysts with different MoO<sub>3</sub> loadings. Reaction conditions:  $[NO] = [NH<sub>3</sub>] = 1000$  ppm,  $[O<sub>2</sub>] = 3$  vol.%, balance N<sub>2</sub> and  $GHSV = 90,000 h^{-1}$ .

tion temperature over various catalysts. As for  $Mo_{10}Ti$ , a maximum NO conversion of 75.1% was obtained at 450 °C. The introduction of  $CeO<sub>2</sub>$  led to the remarkable increase in NO conversions and broadened the activity temperature windows until the mass ratio of  $CeO<sub>2</sub>/TiO<sub>2</sub>$  was up to 40%. In a wide temperature range of 250–450 °C, NO conversions approximately reached 100% over  $Ce_{40}Mo_{10}Ti$  at the GHSV of 90,000 h<sup>-1</sup>. Further increase in CeO<sub>2</sub> loading resulted in the decrease of NO conversions at low and high temperatures.

#### *3.1.2. Effect of MoO3 loadings*

The effect of  $MoO<sub>3</sub>$  loadings on the SCR activity of Ce-Ti oxides is presented in Fig. 2. It was found that the  $MoO<sub>3</sub>$  loadings had almost no effect on NO conversion (nearly 100%) at 250–450 °C. The similar results were also observed over  $CeO<sub>2</sub> - WO<sub>3</sub>/TiO<sub>2</sub>$ [\[9\]](#page--1-0) and  $V_2O_5$ -WO<sub>3</sub>/TiO<sub>2</sub> catalysts [\[19\].](#page--1-0) MoO<sub>3</sub> or WO<sub>3</sub> supported on TiO<sub>2</sub> was not highly active for the SCR reaction. MoO<sub>3</sub> and WO<sub>3</sub> primarily act as structural and chemical promoters rather than main active species [\[9,19\].](#page--1-0) Compared with the other mixed oxides, the catalytic activity of  $Ce_{40}Mo_{10}Ti$  was higher at temperatures below 250 °C. Therefore,  $Ce_{40}Mo_{10}Ti$  was elected as an optimal catalyst for further studies.
