NO removal

### ABSTRACT

A new bismuth-rich  $\text{Bi}_3\text{O}_4\text{Cl}_x\text{Br}_{1-x}$  solid solution photocatalyst was firstly synthesized through a solid phase conversion method. The X-ray diffraction (XRD), scanning electron microscopy (SEM), energy dispersive spectrometry (EDS), high-resolution transmission electron microscopy (HRTEM), UV–vis diffuse reflectance spectroscopy (DRS), X-ray photoelectron spectroscopy (XPS), and photoluminescence spectroscopy (PL) were used to characterize the physico-chemical properties of samples. Results demonstrated that  $\text{Bi}_3\text{O}_4\text{Cl}_{0.5}\text{Br}_{0.5}$  had a higher activity than that of  $\text{Bi}_3\text{O}_4\text{X}$  ( $\text{X}=\text{Cl}, \text{Br}$ ) for photocatalytic NO removal. The valence band XPS and photoelectrochemical analyses, theoretical calculation and scavenger trapping experiment indicated that  $\text{Bi}_3\text{O}_4\text{Cl}_{0.5}\text{Br}_{0.5}$  had higher photocatalytic oxidation ability and effective prohibition of photo-induced charged carriers. This study suggested that solid solution should be effective approach to improve the photocatalytic activity of bismuth-rich photocatalysts for air purification.

### 1. Introduction

Environmental and energy crises are the crucial focus for human existence and development. The semiconductor photocatalysis is an efficient route to solve these issues. In the last few decades,  $\text{TiO}_2$  and ZnO as the traditional photocatalysts that exhibited the narrow visible light response scope owing to their broad band gap, which limits the application of sunlight [1,2]. In order to improve the photocatalytic practical application, a multitude of workers devote themselves to researching new photocatalytic materials. For instances, sulfide-based, silver-based, and bismuth-based semiconductors photocatalysts were reported [3].

$\text{BiOX}$  ( $\text{X}=\text{Cl}, \text{Br}$  and  $\text{I}$ ) semiconductors were the most important bismuth-based photocatalysts. It displayed outstanding photocatalytic activity due to their unique layered structure with the  $[\text{Bi}_2\text{O}_2]$  slabs intersected by double slabs of halogen atoms [4,5].

For instance, a series of  $\text{BiOX}$  photocatalysts were reported by Zhang's group, which displayed notably photocatalytic property through visible light irradiation [6–9]. Our group also fabricated numerous  $\text{BiOX}$  photocatalysts with superior activities for photocatalytic  $\text{H}_2$  evolution and dye degradation [10–12]. Meanwhile, many strategies, such as facet engineering [14–19], doping [20,21], and coupling [22–25], have been used to improve the  $\text{BiOX}$  practical application. Recently, the strategies of solid solution, and bismuth-rich were used to improve the photocatalytic activity and stability of  $\text{BiOX}$ . Solid solution is alloy phase in which the solute atoms dissolve into the solvent lattice and remain the solvent type. And our previous work proved that solid solution can enhance exciton photocatalytic process for effective pollutant degradation [26]. For  $\text{Bi-O-X}$  photocatalytic materials,  $\text{BiOCl}_x\text{I}_{1-x}$ ,  $\text{BiOBr}_x\text{I}_{1-x}$ ,  $\text{BiOCl}_x\text{Br}_{1-x}$  were prepared by solvothermal method. And they displayed more excellent photocatalytic activity for dye degradation than the corresponding monomers [27–29]. For bismuth-rich strategy,  $\text{Bi}_5\text{O}_7\text{Br}$  and  $\text{Bi}_5\text{O}_7\text{I}$  can available activated molecular oxygen and nitrogen, respectively [30,31].  $\text{Bi}_{12}\text{O}_{17}\text{X}_2$  ( $\text{X}=\text{Br}$  and  $\text{Cl}$ ) showed effective photocatalytic activities for generation  $\text{H}_2$  and degradation Rhodamine B (RhB) under visible light [32–34]. Photocatalytic reduction of  $\text{Cr(VI)}$  and degradation of dye were

Bai et al., Solid phase fabrication of Bismuth-rich  $\text{Bi}_3\text{O}_4\text{Cl}_x\text{Br}_{1-x}$  solid solution for enhanced photocatalytic NO removal under visible light, Journal of the Taiwan Institute of Chemical Engineers (2017), <https://doi.org/10.1016/j.jtice.2017.10.021>

evaluated by the  $\text{Bi}_{24}\text{O}_{31}\text{X}_{10}$  ( $\text{X}=\text{Br}$  and  $\text{Cl}$ ) [35–38].  $\text{Bi}_4\text{O}_5\text{X}_2$  ( $\text{X}=\text{Br}$  and  $\text{I}$ ) displayed remarkable photocatalytic performance for  $\text{H}_2$  production,  $\text{CO}_2$  conversion, and degradation of 4-tert-butylphenol [39–41]. In this work, the strategies of bismuth-rich and solid solution were combined to enhance the photocatalytic activity of  $\text{BiOX}$ .

One of the most common gaseous pollutants is nitrogen monoxide ( $\text{NO}$ ) [42]. At present, the physical adsorption and thermal catalysis methods are the traditional techniques, which cannot eliminate  $\text{NO}$  at low concentration (ppb) levels in indoor air [43]. Taking into consideration environmental cleaning, photocatalysis has received significant attention, which especially for the decontamination of air pollutants at low concentrations. Recently,  $\text{BiOX}$  was used for  $\text{NO}$  removal, and showed higher efficiency than  $\text{TiO}_2$  system [44]. For example, Dong fabricated the single-crystal nanoplates of  $\text{BiOX}$  ( $\text{X}=\text{Cl}$ ,  $\text{Br}$ ,  $\text{I}$ ) utilizing removal of  $\text{NO}$  [45]. The  $\text{BiOI}$  hollow microspheres were performed by Zhang's group, which applied for the photocatalytic removal of  $\text{NO}$  [46]. The  $\text{BiOBr}$  microspheres also showed exceedingly photocatalysis activity of  $\text{NO}$  removal [42]. However, there is no report on  $\text{Bi}_3\text{O}_4\text{X}$  ( $\text{X}=\text{Cl}$  and  $\text{Br}$ ) photocatalytic activity for  $\text{NO}$  removal. In this work, bismuth-rich  $\text{Bi}_3\text{O}_4\text{Cl}_x\text{Br}_{1-x}$  ( $x=0, 0.15, 0.35, 0.5, 0.65, 0.85, 1$ ) solid solution was firstly synthesized through the solid phase conversion method. The photocatalytic data showed that  $\text{Bi}_3\text{O}_4\text{Cl}_{0.5}\text{Br}_{0.5}$  can remove 60%  $\text{NO}$  within 10 min under visible light irradiation, which has the higher degradation rate than that of pure  $\text{Bi}_3\text{O}_4\text{X}$  ( $\text{X}=\text{Br}$  and  $\text{Cl}$ ).

## 2. Experimental section

### 2.1. Materials

Bismuth nitrate ( $\text{Bi}(\text{NO}_3)_3 \cdot 5\text{H}_2\text{O}$ ), potassium bromide ( $\text{KBr}$ ), potassium chloride ( $\text{KCl}$ ), bismuth oxide ( $\text{Bi}_2\text{O}_3$ ), and ethyl alcohol were purchased from Sinopharm Chemical Reagent Co. Ltd. (Shanghai, China). All materials were of analytic reagent and without further treatment.

### 2.2. Synthesis

**BiOX:**  $\text{BiOX}$  ( $\text{X}=\text{Cl}$ ,  $\text{Br}$ ) was fabricated via the hydrothermal method. Four mmol  $\text{Bi}(\text{NO}_3)_3 \cdot 5\text{H}_2\text{O}$  was dispersed in 35 mL deionized water under stirring,  $\text{KX}$  ( $\text{X}=\text{Br}$  or/and  $\text{Cl}$ ; 4 mmol) was respectively dissolved in another 35 mL deionized water stirring for 30 min. Then  $\text{KX}$  solution was slowly poured into the  $\text{Bi}(\text{NO}_3)_3 \cdot 5\text{H}_2\text{O}$  solution with serially stirring for 30 min. Transferred the suspension solution into a 100 mL Teflon-lined autoclave, kept at  $160^\circ\text{C}$  for 16 h, and cooled to room temperature.  $\text{BiOX}$  was obtained by centrifuging, washing with deionized water and ethyl alcohol several times, and drying at  $60^\circ\text{C}$  for 12 h.

**$\text{Bi}_3\text{O}_4\text{Cl}_x\text{Br}_{1-x}$ :**  $\text{Bi}_3\text{O}_4\text{Br}_x\text{Cl}_{1-x}$ ,  $\text{Bi}_3\text{O}_4\text{Cl}$ , and  $\text{Bi}_3\text{O}_4\text{Br}$  were synthesized through the solid-state reaction with  $\text{Bi}_2\text{O}_3$  and  $\text{BiOX}$ . Stoichiometric proportion of 2 mmol  $\text{Bi}_2\text{O}_3$  and 2 mmol  $\text{BiOX}$  ( $\text{X}=\text{Br}$ , or/and  $\text{Cl}$ ) were mixed with grinding and annealed at  $600^\circ\text{C}$  for 6 h with the  $5^\circ\text{C}/\text{min}$  heating rate, and then chilled to room temperature.

### 2.3. Characterization

X-ray diffraction (XRD) analyzed the phase and crystal structure of the samples was conducted by a Bruker D8 diffractometer using  $\text{Cu K}\alpha$  radiation, and the scanning region was from  $5^\circ$  to  $70^\circ$  with the  $2\theta$  sweep speed of  $6^\circ/\text{min}$ . Morphology of the photocatalysts was observed by a Quanta 450 scanning electron microscopy (SEM) and energy dispersive spectrometer (EDS). Transmission electron microscopy (TEM) and high-resolution transmis-

Fig. 1. XRD patterns of  $\text{Bi}_3\text{O}_4\text{Cl}_x\text{Br}_{1-x}$  ( $x=0, 0.15, 0.35, 0.5, 0.65, 0.85, 1$ ): (a)  $5^\circ$ – $70^\circ$ , and (b)  $18^\circ$ – $23^\circ$ .

sion electron microscopy (HRTEM) were obtained by a JEOL JEM-2100F (UHR) field emission transmission electron microscopy. UV-vis diffuse reflectance spectroscopy (DRS) of samples were obtained by a UV-vis spectrometer (Perkin Elmer, Lambda 650 s,  $\text{BaSO}_4$  as a reference) with a scanning range of 200–800 nm. X-ray photoelectron spectroscopic (XPS) results of samples was determined by a Thermo Scientific ESCALAB 250XI X-ray photoelectron spectrometer ( $\text{Al K}\alpha$ , 150 W, and  $\text{C1s}$  284.6 eV). PL spectra of the samples were determined by a FLS920 Multifunction Steady State and Transient State Fluorescence Spectrometer (Edinburgh Instruments) at room temperature.

### 2.4. Photocatalytic $\text{NO}$ removal experiments

Photocatalytic  $\text{NO}$  removal experiments were conducted at room temperature in a consecutive flow quartz reactor ( $H=10$  cm;  $L=30$  cm;  $W=15$  cm). In the middle of the reactor, putted a sample dish (diameter, 12 cm) including the 0.12 g of sample was unrolled on it. A 30 Watt LED lamp ( $\lambda=448$  nm) was used as the simulated visible light source.  $\text{NO}$  gas was from a compressed gas cylinder at a concentration of 48 ppm  $\text{NO}$  ( $\text{N}_2$  balance, BOC gas) with traceable National Institute of Standards and Technology (NIST) standard. Diluted the initial concentration of  $\text{NO}$  to about 600 ppb by the air supplied by a zero air generator (Thermo Environmental Inc. model 111). The humidity grade of the  $\text{NO}$  flow was kept at 70% by passing the zero air streams through a humidification chamber. The gas streams were pre-mixed totally through
