Abstract Salvo attacking a surface target by multiple missiles is an effective tactic to enhance the lethality and penetrate the defense system. However, existing cooperative guidance laws in the midcourse or terminal course are not suitable for long- and medium-range missiles or stand-off attacking. Because the initial conditions of cooperative terminal guidance that are generally generated from the mid-course flight may not lead to a successful cooperative terminal guidance without proper mid-course flight adjustment. Meanwhile, cooperative guidance in the mid-course cannot solely guarantee the accuracy of a simultaneous arrival of multiple missiles. Therefore, a joint mid-course and terminal course cooperative guidance law is developed. By building a distinct leader-follower framework, this paper proposes an efficient coordinated Dubins path planning method to synchronize the arrival time of all engaged missiles in the mid-course flight. The planned flight can generate proper initial conditions for cooperative terminal guidance, and also benefit an earliest simultaneous arrival. In the terminal course, an existing cooperative proportional navigation guidance law guides all the engaged missiles to arrive at a target accurately and simultaneously. The integrated guidance law for an intuitive application is summarized. Simulations demonstrate that the proposed method can generate fast and accurate salvo attack.

 guidance strategies mostly focus on the terminal guidance phase of missiles, and they are based on the classic Propor- tional Navigation Guidance^{[16](#page--1-0)} (PNG) or the optimal guid- ance[.17](#page--1-0) In 2006, Jeon et al. [1](#page--1-0) derived a closed form of the Impact Time Control Guidance (ITCG) law based on a linear formulation. The ITCG law guides a missile to attack a sta- tionary target at a presetting time. Lee et al. [2](#page--1-0) extended the ITCG law to control both the impact time and the impact angle. In 2010, Jeon and Lee [3](#page--1-0) proposed a Cooperative Pro- portional Navigation (CPN) for many-to-one engagements, which decreases the variance of the time-to-go (time left before hitting) of engaged missiles. Based on ITCG and consensus protocols, Zhao and Zhou [4](#page--1-0) introduced an effective hierarchi- cal cooperative guidance architecture including both central- ized and distributed coordination algorithms. Zou et al. [5](#page--1-0) proposed a distributed adaptive cooperative guidance law for multiple missiles with a heterogeneous leader–follower struc- ture to implement a cooperative salvo attack. Similarly, Zhao et al. [6](#page--1-0) proposed a virtual leader-based scheme that achieves impact time control indirectly by skillfully transforming the time-constrained guidance problem to a nonlinear tracking problem. Zhang et al. [7](#page--1-0) designed a practical Three- Dimensional (3-D) impact time and impact angle control guid- ance law by using a two-stage control approach. Zhang and Ma et al. [8](#page--1-0) designed a feasible Biased PNG (BPNG) law to control the impact time and the impact angle. Based on ITCG, a biased term with the cosine of weighted leading angle was used by Zhang et al. [9](#page--1-0) to guarantee that the Field-Of-View (FOV) constraint is not violated during an engagement. Fur- thermore, Zhang and Wang et al. [10](#page--1-0) proposed a distributed cooperative scheme to ensure a convergence to the same J. ZENG et al.

 nication network. Zhao and Zhou [11](#page--1-0) presented unified cooper- ative strategies for the salvo attack of multiple missiles, and developed guidance laws against both stationary and maneu- vering targets. Lately, Zhao et al. [12](#page--1-0) proposed an effective 3- D guidance law to perform cooperative engagements of multi- ple missiles against both a stationary target and a maneuvering 67 one.

60 impact time under an either fixed or switching sensing/commu-

 From another point of view, some scholars have concen-69 trated on cooperative guidance in midcourse.^{[15,18–22](#page--1-0)} Morgan [15](#page--1-0) addressed a midcourse guidance law which ensures a suffi- ciently small Zero Effort Miss (ZEM) at the handover moment and optimizes an energy cost function. Since a sooner attack is preferred in a battlefield, Indig et al. [18](#page--1-0) presented near-optimal solutions for minimum-time midcourse guidance of missiles with an angular constraint in both planar and spatial cases. As shown in the simulations work of Indig et al., flight paths closely approximate the optimal Dubins path¹⁹ which is the time-optimal path for vehicles with a constant velocity. Tanil [20](#page--1-0) firstly made midcourse cooperative waypoint path planning for multi-missile salvo attack by adopting an evolutionary spe- ciation approach. Obstacle avoidance and simultaneous arrival are equally emphasized in the work of Tanil, but the turning radius constraint is neglected. Shima et al. [21](#page--1-0) solved a simulta- neous interception problem of multiple vehicles, and proposed three path elongation algorithms, but all the elongated paths have curved turnings at the end of flights, which is not suitable for midcourse guidance. The acquisition phase is considered in our proposal, and all the elongated paths have straight head- ings toward a target at the end of flights. Yao et al. [23](#page--1-0) pre-sented elongated Dubins paths with bounded curvatures and

preset lengths. However, the leader-follower scheme in our 91 proposal ensures a soonest salvo attack. 92

The satisfactory effect of aforementioned guidance laws has 93 been proven in either the mid-course or the terminal course. 94 However, the two courses should not be considered separately 95 in a cooperative guidance since a terminal guidance with a 96 closed-loop command is indispensable for a precise attack. 97 Meanwhile, the initial conditions of the terminal course are gen- 98 erated from the midcourse flight, and there are constraints on the 99 initial conditions of the terminal course cooperation as follows: 100

- (1) The detection range constraint of seeker: all participant 101 missiles should be in certain ranges from the target at the 102 moment when the cooperative terminal guidance starts. 103
- (2) The FOV constraint of seeker: all the included angles 104 between Line-Of-Sight (LOS) and missile headings 105 should not violate the FOV constraints throughout the 106 cooperative terminal course. 107

In short words, all the engaged missiles should have accom- 109 plished the acquisition and the handover process at the initial 110 moment of the cooperative terminal guidance. Moreover, the 111 Time-To-Go (TTG) differences among them should be small 112 enough. 113

These initial constraints above are not innately satisfied 114 without the mid-course cooperation, since the differences 115 between the predicted flight times among the missiles cannot 116 be eliminated from the launching moment to the terminal 117 course. Therefore, the demand on a joint midcourse and termi- 118 nal course cooperative guidance emerges. Besides, a joint coop- 119 erative guidance is required for long-range cruise missiles and 120 those for stand-off attack. The joint mid-course and terminal 121 course cooperative guidance at least has the following three 122 advantages: 123

- (1) Since missiles are relatively far from the target in the 124 mid-course flight, the length adjustment for a missile's 125 path has a much wider range as compared with that in 126 the terminal phase. 127
- (2) The heading of a missile is not constrained by the FOV 128 in the midcourse. 129
- (3) The terminal course flight is in the core defense area of 130 the opponent. As compared with maneuvering in the ter- 131 minal course, elongating a flight path in the midcourse 132 has a lower risk. 133

Taking both multi-missile handover conditions and the 135 soonest salvo attack into consideration, this paper utilizes 136 Dubins paths and proposes a coordinated path planning 137 method under a novel leader-follower framework. Unlike com- 138 mon leader-follower frameworks, $5,6$ the framework built in this 139 paper is for synchronizing the expected arrival time of all 140 engaged missiles by path planning, rather than simply unifying 141 the missile speed, heading error, and sight distance. The 142 planned flight paths for all missiles not only follow the dynam- 143 ics of these missiles, but also achieve a soonest salvo attack. 144

The innovations of this paper are as follows: 145

(1) To our best knowledge, it is the first time to propose a 146 joint cooperative guidance law from the perspective of 147 satisfying the constraints on the initial conditions of 148 cooperative terminal guidance by incorporating mid- 149 Download English Version:
