This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

Highlights

- We propose the multidimensional scaling based on Kronecker-delta dissimilarity (MDSK) to analyze multivariate statistical problems, in which symbolic process is needed.
- We have shown through experiments that the length of the data does not affect the quality of method, and it is always a better choice than Multidimensional scaling(MDS) methods with other alternative dissimilarity measurement based on spatial distance.
- Our experiments show that this method has obvious advantages in noisy environment than Multidimensional scaling (MDS) methods with other alternative dissimilarity measurement based on spatial distance.
- Our analysis reveals a clear clustering of eighteen indices from diverse stock markets. All methods mentioned in this paper provide similar classifications, but only MDSK separates the BVSP as a single group, thus, one can take it apart from the indices from the North America. It implies that MDSK is more sensitive.
