Keywords: Global solar radiation Support vector machine Air temperatures Distance Altitude

ABSTRACT

Exploring novel methods for estimation of global solar radiation from air temperature has been being a focus in many studies. This paper evaluates the transferability of support vector machines (SVM) for estimation of solar radiation in subtropical zone in China. Results suggest that solar radiation at one site (estimation site) could be well estimated by SVM model developed at another site (source site). The accuracy of estimation is affected by the distance and temperature difference between two sites, and altitude of source site. Higher correlations between RMSE of SVM and distance, and temperature differences are observed in northeastern region, increasing the reliability and confidence of SVM model developed at nearby stations. While lower correlations between RMSE and distance, and temperature differences are observed in southwest plateau region. When the altitude of estimation site is lower than 1200 m, RMSE show logarithm relationship with altitude of source sites where the altitude are lower than that of estimation site. Otherwise, RMSE show linearly relationship with altitude of source sites where the altitude are higher than 200 m but lower than that of the estimation site. This result suggests that solar radiation could be also estimated using SVM model developed at the site with similar but lower altitude. Based on these results, a strategy that takes into account the climatic conditions, topography, distance, and altitude for selecting a suitable source site is presented. The findings can guide and ease the appropriate choice of source sites for estimation of solar radiation at estimation site.

1. Introduction

The importance of global solar radiation in ecology, agriculture, environment and the associated researches has been well documented [1–3]. However, due to the cost of measuring equipment and its difficult maintenance and calibration, lack of sufficient solar radiation data has been reported in many countries like USA [4,5], United Kingdom [6], Egypt [7], India [8], France [9], Greece [10], Italy [11] and China [12–14]. On the contrary, air temperature is routinely measured at most meteorological stations. In this context, great efforts have been made to estimate

solar radiation using air temperature [15,16]. Hargreaves and Samani [15] proposed a model (H–S model) using air temperature range, several modified versions were developed and validated in many places around the world [17–20]. Although some authors claimed that their new versions outperformed the original model, this may not always be the cases in many studies even when other commonly measured meteorological variables are taken into account [4,13,21,22]. Bristow and Campbell [16] developed a model (B–C model) as exponential function of temperature range. Numerous modifications centered on tuning the parameters of B–C model have been made [23–25]. However, many evaluations suggested that such modifications were generally not effective and yielded little or no improvement [26–28].

Accurate estimation of solar radiation has been being a major goal for solar energy practitioners, climatologists and all concerned scientists [29]. It seems that H–S, B–C models and their revised

versions, as well as other empirical models, have far overreached their predictive limits. Therefore, exploring new methods has became the focus of many studies in recent years [30–39].

Recently, as the development of computational technology and sophisticated statistical methods, a novel machine learning method, support vector machine (SVM), has been widely applied in computer [40], environment [41,42] and hydrology researches [43], and proven to be a robust algorithm in classification [44]. regression [45.46] and forecasting [47]. Many studies proved that SVM is superior to Neural Network and traditional statistical models [48-50]. Despite successes in many fields, there is not any application in estimation of solar radiation until our work investigated the feasibility of SVM using air temperatures at Chongqing, China [3]. While it is still needed to research further to solve the problem how to apply SVM model to the site where no solar radiation data is available. One possible alternative is to substitute training data from nearby representative meteorological stations. It was proposed by Allen et al. [51] as a possible way of replacing missing data when calculating daily evapotranspiration. However, there is lack of explicit guidance on appropriate choice of the representative stations, which may result in arbitrariness in choosing a source site that provides data for constructing SVM model for solar radiation estimation at the estimation site. Thus, the transferability of SVM model is investigated.

The present study is carried out in China's subtropical zone which plays an important role in ecological, agricultural and climate researches in the world. However, there are only 32 meteorological stations measuring global solar radiation. On the contrary, more than 700 stations have records of air temperatures, offering an important alternative to deriving solar radiation due to the widely availability of temperature data. Some works validated the temperature-based models for this area [52–54], and a few revised models were developed [13,52]. However, these new versions were found to give similar performances with the original ones at many sites [13,52,55]. Apart from model accuracy, one major limitation is that calibration of those empirical models is constrained by unavailability of solar radiation data, limiting

applications of those models to other site where solar radiation data is not available. Therefore, exploring model developed at source site for estimating solar radiation at estimation site is of vital importance and significance, not only for China's subtropical zone but also for other regions. The main objectives of this study
