Abstract:

The time-dependent crack initiation from the interface free-edge of adhesively bonded axisymmetric columnar butt joints (epoxy/SUS, edge shape: 90°/90°) was investigated in detail. With the change of applied stress level,  $\sigma_n$ , the butt joints exhibited crack initiation life,  $t_C$ , that varied about four orders of seconds ( $10^2 \sim 10^6$  s). Such a clear time-dependent life property was then studied in terms of the fracture mechanics. The near-edge stress/strain field at the crack initiation was numerically evaluated with the finite element method (FEM) by applying the time-hardening creep law to the epoxy resin. It was found that the critical asymptotic stress field along the interface represented by the combination of two parameters,  $\lambda_\sigma^{cr}$  (creep stress singularity index) and  $K_\sigma^{cr}$  (creep stress intensity factor), satisfies a unique relation irrespective of  $(\sigma_n, t_C)$  sets. The same tendency was also confirmed when the near-edge *total* strain field parameters were employed. These results indicate that the  $K$ - $\lambda$  criterion, originally developed for static fracture problems, still holds its validity in the time domain.

Key words: Interface; Free-edge; Crack initiation; Time-dependent; Fracture criterion
