This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

Highlights

- Four impact tests on reinforced concrete panels by Schedule 40 pipes were simulated using the Lagrangian and SPH formulations to validate a numerical model.
- The Lagrangian formulation reasonably predicted panel response and local damage to the thinner panels but predicted less well the results of tests on thicker panels.
- The SPH model reasonably predicted panel response and local damage for the range of panel thicknesses chosen.
- Lack of information and metadata from the experiments poses a challenge to fully validate a numerical model for impact analysis.
