Abstract:

We employ data from up to 125 countries during the 1970-2009 period to explore the relationship between globalization and labor share. Existing studies report a negative relationship between trade and investment flows and labor shares. While we also find that economic flows are often negatively related to labor shares, measures of social globalization tend to be positively related to labor shares. While greater mobility of goods and capital may be associated with increases in capital's bargaining power, all else equal, greater flows of information, ideas, and people may increase the bargaining power of workers.

Keywords: labor share, capital share, globalization, functional distribution of income
