## Abstract

A non-cooperative solution, the Equilibrium in Secure Strategies (EinSS), is defined as an extension of the Nash equilibrium in pure strategies, and is meant to solve games where players are “cautious,” *i.e.*, looking for secure positions and avoiding threats. This concept abstracts and unifies *ad hoc* solutions already formulated in various applied economic games that have been discussed extensively in the literature. A general existence theorem is provided and then applied to the price-setting game in the Hotelling location model, to Tullock’s rent-seeking contests, and to Bertrand-Edgeworth duopoly. Finally, competition in the insurance market game is re-examined and the Rothchild-Stiglitz-Wilson contract is shown to be an EinSS even when the Nash equilibrium breaks down.

## 1. Introduction

There are well-known economic games where a Nash-Cournot equilibrium does not exist. Examples include the Bertrand-Edgeworth duopoly model<sup>1</sup>, Hotelling’s game of price competition on the line when the sellers locations are close<sup>2</sup>, Tullock’s rent-seeking game with the success function parameter greater than two<sup>3</sup>, and Rothchild and Stiglitz’s game of competitive insurance markets with adverse selection<sup>4</sup>. This existence problem was highlighted by Dasgupta and Maskin in their seminal paper (1986). They proved the existence of mixed strategy Nash equilibria for a family of games with discontinuous payoff functions covering all mentioned models. However, these equilibria are not easy to characterize in
