Abstract

An empirical study of the Brazilian option market is presented in light of three option pricing models, namely the Black-Scholes model, the exponential model, and a model based on a power law distribution, the so-called q -Gaussian distribution or Tsallis distribution. It is found that the q -Gaussian model performs better than the Black-Scholes model in about one third of the option chains analyzed. But among these cases, the exponential model performs better than the q -Gaussian model in 75% of the time. The superiority of the exponential model over the q -Gaussian model is particularly impressive for options close to the expiration date, where its success rate rises above ninety percent.

Keywords: Option pricing, non-Gaussian option models, power law distribution, exponential distribution

1. Introduction

Options are important financial instruments that can be used for both investment strategies and risk management and they represent nowadays a multi-trillion market. An option is a derivatives contract that gives its
