Abstract

We develop tools for computing equilibrium bond prices for the discrete-time version of the Vayanos-Vila (2009) model. With the maturity structure included in pricing factors, factor loadings for equilibrium bond yields depends critically on parameters describing maturity structure dynamics and other model parameters. An illustrative example shows that the effect on the yield curve of a supply shock originating in a given maturity, although hump-shaped around the originating maturity, is to change yields broadly across all maturities.

Keywords: Vayanos-Vila model; computation; maturity structure; yield curve; risk premia.

JEL classification: E43, E58, G12.

This paper was formerly circulated as “Affine Term Structure Pricing with Bond Supply As Factors” (Center for Quantitative Economic Research Working Paper 16-01, Federal Reserve Bank of Atlanta, April 2016). I thank Junko Koeda for posing the question treated here and a reviewer for this journal for insightful comments. The research reported here was supported by grants-in-aid from the Ministry of Education, Culture, Sports, Science, and Technology of the Japanese government (grant number 25285097 and 26870124).
