9 Abstract

10 A statistical correlation was established among the molecular weight distribution patterns of
11 unreduced gluten proteins and physicochemical, rheological and bread-making quality
12 characteristics of wheat varieties. Size exclusion chromatography fractionated the gluten proteins
13 apparently into five peaks. Peak I signified glutenins (30–30 kDa), peak II as gliadins (20–55
14 kDa), peak III as very low molecular weight monomeric gliadins (10–28 kDa), peak IV and V,
15 collectively, as albumins and globulins (<10 kDa). Peaks I and II had appreciable effects on
16 dough development time ($r = 0.830^{**}$ and $r = -0.930^{**}$) and dough stability ($r = 0.901^{**}$ and r
17 $= -0.979^{**}$). Peak I was associated with R/E ratio ($r = 0.745^{**}$), gluten index ($r = 0.959^{**}$), and
18 gliadin/glutenin ratio ($r = -0.952^{**}$), while peak II influenced inversely as expected. Peak I
19 exhibited positive statistical significance with bread loaf volume ($r = 0.848^{**}$); however, peak II
20 had negative ($r = -0.818^{**}$) impact. Bread firmness increased with increment in peak II ($r =$
21 0.625^{**}), and decreased with accretion in peak I ($r = -0.623^{**}$).
