Highlights

- RPLC×HILIC-MS method developed for untargeted lipidomic analysis of human plasma
- Method provided separation of the major lipid classes and a peak capacity of approximately 100,000
- LC-TIMS-MS method developed for lipidomic profiling of human plasma
- Two multidimensional separation platforms (LC×LC-MS vs. LC-TIMS-MS) were compared
- Main advantages and drawbacks of both approaches are discussed

Abstract

Recent advancements in separation science have resulted in the commercialization of multidimensional separation systems that provide higher peak capacities and, hence, enable a more-detailed characterization of complex mixtures. In particular, two powerful analytical tools are increasingly used by analytical scientists, namely online comprehensive two-dimensional liquid chromatography (LC×LC, having a second-dimension separation in the liquid phase) and liquid chromatography-ion mobility-spectrometry (LC-IMS, second dimension separation in the gas phase).

The goal of the current study was a general assessment of the liquid-chromatography – trapped-ion-mobility – mass spectrometry (LC-TIMS-MS) and comprehensive two-dimensional liquid
