The synapse is a particularly important compartment of neurons. To reveal its molecular 23 characteristics we isolated whole brain synaptic (sMito) and non-synaptic mitochondria (nsMito) 24 from the mouse brain with purity validated by electron microscopy and fluorescence activated 25 cell analysis and sorting. Two-dimensional differential gel electrophoresis and mass spectrom- 26 etry based proteomics revealed 22 proteins with significantly higher and 34 proteins with 27 significantly lower levels in sMito compared to nsMito. Expression differences in some oxidative 28 stress related proteins, such as superoxide dismutase [Mn] (Sod2) and complement component 29 1Q subcomponent-binding protein (C1qbp), as well as some tricarboxylic acid cycle proteins, 30 including isocitrate dehydrogenase subunit alpha (Idh3a) and ATP-forming β subunit of 31 succinyl-CoA ligase (SuccLA2), were verified by Western blot, the latter two also by immunohis- 32 tochemistry. The data suggest altered tricarboxylic acid metabolism in energy supply of synapse 33 while the marked differences in Sod2 and C1qbp support high sensitivity of synapses to oxidative 34 stress. Further functional clustering demonstrated that proteins with higher synaptic levels are 35 involved in synaptic transmission, lactate and glutathione metabolism. In contrast, mitochon- 36 drial proteins associated with glucose, lipid, ketone metabolism, signal transduction, morpho- 37 genesis, protein synthesis and transcription were enriched in nsMito. Altogether, the results 38 suggest a specifically tuned composition of synaptic mitochondria. 39

Biological significance 41

Neurons communicate with each other through synapse, a compartment metabolically 42 isolated from the cell body. Mitochondria are concentrated in presynaptic terminals by 43

active transport to provide energy supply for information transfer. Mitochondrial 44 composition in the synapse may be different than in the cell body as some examples 45 have demonstrated altered mitochondrial composition with cell type and cellular function 46 in the muscle, heart and liver. Therefore, we posed the question whether protein 47 composition of synaptic mitochondria reflects its specific functions. The determined 48 protein difference pattern was in accordance with known functional specialties of high 49 demand synaptic mitochondria. The data also suggest specifically tuned metabolic fluxes 50 for energy production by means of interaction with glial cells surrounding the synapse. 51 These findings provide possible mechanisms for dynamically adapting synaptic mitochondrial 52 output to actual demand. In turn, an increased vulnerability of synaptic mitochondria to 53 oxidative stress is implied by the data. This is important from theoretical but potentially also 54 Q3 from therapeutic aspects. Mitochondria are known to be affected in some neurodegenerative 55 and psychiatric disorders, and proteins with elevated level in synaptic mitochondria, e.g. C1qbp 56 represent targets for future drug development, by which synaptic and non-synaptic mito- 57 chondria can be differentially affected. 58

Q4 1. Introduction

75 Neuronal synapses are cell compartments highly separated 76 from the cell body in functional and metabolic sense [1]. The 77 energy consumption of synapses is extremely high if nor- 78 malized to volume in order to keep the membrane potential 79 [2], and support neurotransmission [3] and local protein syn- 80 thesis [4–6]. To meet the metabolic demand, synapses are 81 surrounded by glial elements, which support synaptic metab- 82 olism [7]. In turn, sMito possess characteristics of highly 83 intensive and dynamic ATP production and intensive oxygen 84 metabolism [8–10]. Functionally, synapse is extremely sensi- 85 tive to oxidative stress and selectively vulnerable in several 86 diseases [11]. While a compartmentalization of metabolism 87 between neuronal and glial cells exists for the cell bodies, too, 88 there are specific differences for the synapse. Transporters 89 and enzymes localized in presynaptic terminals and adjacent 90 glial processes allow the uptake of amino neurotrans- 91 mitters glutamate and GABA into astrocytes and the constant 92 supply of glutamine from astrocytes to the terminals in 93 exchange [12,13]. The synaptic transmission related function- 94 al differences suggest that constitutional differences exist 95 between sMito and nsMito. In addition, an increasing number 96 of studies support the pivotal role of mitochondria in 97 pathological changes in synaptic function in neurodegener- 98 ative diseases [14–18]. Despite its significance, however, our 99 knowledge on the protein levels in sMito is seriously limited. 100 So a systematic and reliable proteomics study on sMito is a 101 real need for better understanding of synaptic functions in 102 health and disease. The key for the investigation of sMito by 103 proteomics is a reliable and validated separation of synaptic 104 mitochondria from the rest of the mitochondria. Thus, we 105 used independent methods for the validation of sMito and 106 nsMito in the present study.

107 Intracellular positioning dependent alterations in mito- 108 chondrial protein composition have been revealed in the 109 muscle, heart and liver where basic functions of mitochondria 110 (e.g. energy metabolism and the biosynthesis of metabolites) 111 are fine-tuned according to local requirements [19]. Thus, the 112 mitochondria of a certain tissue can be clustered by function 113 and oxygen consumption [20]. The mechanisms of protein 114 network tuning of mitochondria are the transport of different

amounts of proteins into the mitochondria and the altered 115 profile of mitochondrial gene expression and local protein 116 synthesis [21]. In synapses, beside the mitochondrial protein 117 synthesis, presynaptic nerve terminals also contain a local 118 cytosolic protein synthesis system transcribing a heteroge- 119 neous population of mRNAs supplied by mRNA transport 120 system [22–25]. Synaptic translation of mRNAs is known to 121 play a critical role in the functional regulation of sMito [26–29]. 122 Thus, the non-nuclear protein synthesis and synaptic protein 123 sorting already revealed in the synapse can provide the basis 124 of creating specific protein composition in sMito. However, it 125 is unknown what kinds of metabolic pathways are particu- 126 larly the characteristic of the synapse. Therefore, in the 127 present study, we addressed the difference in the protein 128 content between sMito and nsMito using two-dimensional 129 differential gel electrophoresis. We identified 103 protein 130 spots whose levels differed between sMito and nsMito and 131 identified the proteins with mass spectrometry. Since the 132 preparation of mitochondria is critically important, we 133 checked the purity and integrity of the mitochondria using 134 electron microscopy and fluorescence activated cell analysis 135 and sorting (FACS). Furthermore, some of the highest protein 136 changes including ATP-forming β subunit of succinyl-CoA 137 ligase (SuccLA2), mitochondrial isocitrate dehydrogenase sub- 138 unit alpha (Idh3a), superoxide dismutase [Mn] (Sod2), and 139 complement component 1Q subcomponent-binding protein 140 (C1qbp) were confirmed by Western blot and the former 2 also 141 by immunohistochemistry. 142

2. Materials and methods 143

2.1. Animals 145

146 Six three-month-old Balb/c mice were used for analytical and 147 another twelve for preparative proteomic experiments, five for 148 electron microscopy, five for light-microscopic immunohisto- 149 chemistry and two for electron microscopic immunolabeling. 150 Animals were kept under a 12 h-light-dark cycle (light was on 151 from 08.00 AM to 08.00 PM) and food and water were supplied *ad* 152 *libitum*. The handling and experimentation of all animals 153 conformed to The Code of Ethics of the World Medical
