## ABSTRACT

Three new chromium-based ammine borohydrides were synthesized by ball milling  $\text{CrCl}_3 \cdot n\text{NH}_3$  ( $n = 3-5$ ) and  $\text{LiBH}_4$  in a molar ratio of 1:3. Thermogravimetric analysis–mass spectrometry (TG–MS) measurements showed that the chromium-based ammine borohydrides release  $\text{H}_2$  in the temperature range of 100–170 °C, concurrent with the evolution of a small amount of  $\text{NH}_3$  evolution. The dehydrogenation purity increases with decreasing coordination number of ammonia, with the highest dehydrogenation purity (91.8 mol%) achieved for  $\text{CrCl}_3 \cdot 3\text{NH}_3/3\text{LiBH}_4$ . Further improvement on the dehydrogenation of  $\text{CrCl}_3 \cdot 3\text{NH}_3/3\text{LiBH}_4$  is conducted by the addition of  $\text{ZnCl}_2$ . The 0.5 mol  $\text{ZnCl}_2$  assisted sample is able to release 7.4 wt.% of hydrogen with a purity of 98.8 mol%.

## Introduction

Storage of hydrogen safely and efficiently is one of the pivotal obstacles to the wide use of hydrogen-fueled vehicles [1]. The conventional hydrogen storage methods, i.e., gaseous hydrogen compression and liquefaction of hydrogen, have the disadvantages such as high pressure involved and energy-consuming process [2,3]. Thus, as an alternative to gas and liquid hydrogen storage, many chemical hydrogen storage systems have been developed by researchers over the past few decades, such as metal hydrides [4,5], complex chemical hydrides [6–11] and B–N-based [12–14] hydrogen storage materials. Among them, ammine metal borohydrides (AMBs),

$\text{M}(\text{BH}_4)_m \cdot n\text{NH}_3$  ( $\text{M} = \text{Li}$  [15,16],  $\text{Mg}$  [17],  $\text{Ca}$  [18,19],  $\text{Al}$  [20,21],  $\text{Y}$  [22],  $\text{Ti}$  [23],  $\text{Nb}$  [24],  $\text{Sc}$  [25],  $\text{V}$  [25] etc.) have attracted great attentions due to their high hydrogen gravimetric densities and low dehydrogenation temperature. It has been demonstrated that the low dehydrogenation temperature is based on the combination reaction between  $\text{N-H}^{\delta+}$  and  $\text{B-H}^{\delta-}$  [26].

Previous studies have demonstrated that there is a correlation between the electronegativity ( $\chi_p$ ) of the metal center  $\text{M}$  and the dehydrogenation temperature in AMBs [15–25]. Generally, an increase in the value of  $\chi_p$  leads to a decrease in the desorption temperature of ammine metal borohydrides. This provides a viable way for developing new ammine metal borohydrides by controlling the  $\chi_p$  of the cation. Cr has a  $\chi_p$  of 1.66, indicating that the great potential of chromium-based

amine borohydrides towards favorable dehydrogenation properties. In addition, the coordination number of  $\text{NH}_3$  is another crucial factor in tuning the dehydrogenation properties, as it could affect the crystal and electronic structure of AMBs [17,21,23]. For example, the dehydrogenation temperature of  $\text{Al}(\text{BH}_4)_3 \cdot n\text{NH}_3$  ( $n = 5, 4, 3$  and  $2$ ) lowered with the decrease of the coordination number of  $\text{NH}_3$  [21].

Herein, we reported the synthesis of chromium-based ammine borohydrides,  $\text{CrCl}_3 \cdot n\text{NH}_3/3\text{LiBH}_4$  ( $n = 3, 4$  and  $5$ ), via ball-milling  $\text{CrCl}_3 \cdot n\text{NH}_3$  ( $n = 3, 4$  and  $5$ ) with  $\text{LiBH}_4$  in a molar ratio of 1:3, respectively, and their dehydrogenation properties and mechanism were studied in detail.

## Experimental

### Reagents and synthesis

Anhydrous  $\text{LiBH}_4$  (95%),  $\text{CrCl}_3$  (99.99%),  $\text{ZnCl}_2$  (99.9999%) from Sigma–Aldrich were used as received without further purification, while  $\text{NH}_3$  (Alfa Aesar) was purified by soda lime before use. All solid samples were handled in a glovebox equipped with a recirculation and regeneration system, which maintained the oxygen and water concentrations below 1 ppm.

### Preparation of $\text{CrCl}_3 \cdot 5\text{NH}_3$

$\text{CrCl}_3 \cdot 5\text{NH}_3$  was first prepared by reacting  $\text{CrCl}_3$  with  $\text{NH}_3$  in liquid ammonia according to Eq. (1). Approximately 0.5 g of  $\text{CrCl}_3$  was transferred to the reaction vessel under an argon atmosphere. After the argon was evacuated, purified dry  $\text{NH}_3$  gas was purged into the flask with  $\text{CrCl}_3$  and was kept under 4 atm  $\text{NH}_3$  atmosphere overnight under ice-water bath until  $\text{CrCl}_3$  was saturated. After excessive ammonia was evacuated, the molar ratio of  $\text{NH}_3$  to  $\text{CrCl}_3$  was determined gravimetrically to be 5.0, confirming the formation of  $\text{CrCl}_3 \cdot 5\text{NH}_3$ .

### Preparation of ammine chromium borohydrides

These ammine chromium borohydrides were prepared by ball-milling the mixtures of  $\text{CrCl}_3 \cdot n\text{NH}_3$  ( $n = 3, 4$  and  $5$ ) and  $\text{LiBH}_4$  in a molar ratio of 1:3 using Planetary QM-3SP2 with a ball-to-powder ratio of 30:1. For the  $\text{ZnCl}_2$  added samples,  $\text{CrCl}_3 \cdot 3\text{NH}_3:\text{LiBH}_4:\text{ZnCl}_2$  with a mole ratio of 1:3: $n$  ( $n = 0.25$  and  $0.5$ ) was ball milled as above conditions. To avoid the temperature of the powder in the vessel increasing, the milling process was carried out by alternating 12 min of milling and 6 min of rest. The ball milling rate is 200 rpm.

### Instrument and analysis

Temperature-programmed-desorption (TPD) were performed to measure the dehydrogenation behavior on a semi-automatic Sievert's apparatus. A sample with a mass of approximately 0.1 g was heated from room temperature to  $250^\circ\text{C}$  at a heating rate of  $5^\circ\text{C min}^{-1}$  under argon atmosphere (1 bar).

The contents of  $\text{H}_2$  and  $\text{NH}_3$  in the emission gas were determined using gravimetric and volumetric results. Firstly, the mass percent ( $W_p$ ) and mole per gram ( $M_p$ ) of gas released from the samples were calculated from the weights of the samples and volumetric results, then the mole proportion of  $\text{H}_2$  ( $C_{\text{H}_2}$ ) and  $\text{NH}_3$  ( $C_{\text{NH}_3}$ ) can be calculated from the following two equations,

$$C_{\text{H}_2} + C_{\text{NH}_3} = 1 \quad (2)$$

$$(C_{\text{H}_2} \times 2.02 + C_{\text{NH}_3} \times 17.03) \times M_p = W_p \quad (3)$$

Simultaneous thermal gravimetric analysis and mass spectrometry (TGA-MS, QMS 403) were conducted to investigate the hydrogen release property of the as-prepared samples. Typically, 5–10 mg quantities of the sample were heated from room temperature to  $250^\circ\text{C}$  under 1 atm argon atmosphere with a heating rate of  $5^\circ\text{C min}^{-1}$ .

Synchrotron X-ray powder diffraction data were collected on the Powder Diffraction Beamline, Australian Synchrotron by a Mythen-II detector with a wavelength of  $0.7286 \text{ \AA}$  and  $1.0329 \text{ \AA}$ . For phase identification and structure determination, the samples were loaded into a pre-dried 0.7 mm boron-silica glass capillary inside an argon-filled glove-box. The capillary was sealed with vacuum grease for X-ray diffraction measurements.

Fourier transform infrared (FT-IR) (Magna-IR 550 II, Nicolet) analyses were conducted to confirm the chemical bonds in the sample. Products were pressed with KBr and then loaded into a sealed chamber with a  $\text{CaF}_2$  window for the measurement. Anhydrous KBr was used as a pellet material.

## Results and discussion

### Synthesis and characterization of ammine chromium chlorides

The thermal decomposition behavior of  $\text{CrCl}_3 \cdot 5\text{NH}_3$  is shown in Fig. 1. It distinctly shows a three-stage decomposition with

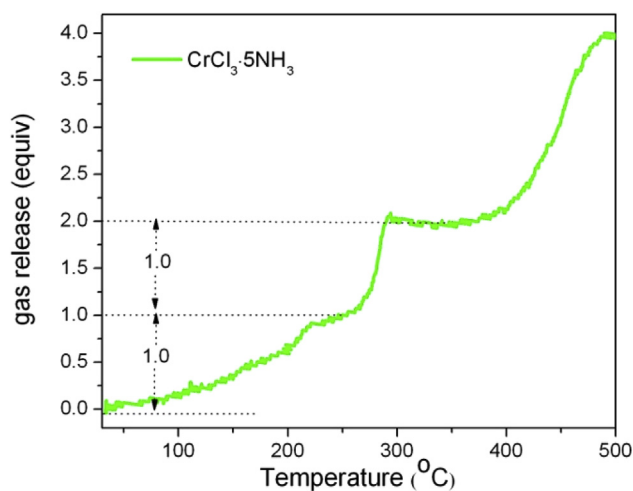

Fig. 1 – TPD result for  $\text{CrCl}_3 \cdot 5\text{NH}_3$  with a heating rate of  $5^\circ\text{C min}^{-1}$ .
