Review

The role of gold in transition metal carbonyl clusters

Iacopo Ciabatti*, Cristina Femoni*, Maria Carmela Iapalucci, Silvia Ruggieri, Stefano Zacchini

Crystal structures

ABSTRACT

In this review, the authors describe the role of gold in the chemistry of transition metal carbonyl clusters, a field that has been very active over the past fifty years. Both homo- and heteroleptic Au-containing species of metal carbonyl clusters, fully characterized by X-ray analysis, are discussed across three categories: those which are surface decorated by Au(I) fragments, cluster units connected by naked Au(I) atoms, and Au core-shell species with metallic gold structures embedded in the cluster frameworks.

1. Introduction

Since the very beginning of our civilization, gold has always been considered a substance of great value, but – perhaps owing to its noble character – in-depth study of the chemistry of gold only took off relatively recently. This started with the first organometallic compounds, followed by molecular clusters [1], colloids and nanoparticles (AuNPs) [2], and most recently atomically precise gold nanoclusters [3]. Once the synthesis of AuNPs was fully elucidated [4], countless papers describing their role in medicine [5], biology [6], catalysis and nanotechnology [7] have been published.

This review focuses on the role of gold in the chemistry of transition-metal carbonyl clusters, an active field that began with the pioneering work of Coffey, Lewis and Nyholm [8] who prepared carbonyl complexes containing M–Au bonds (M = Mn, Fe, Co). Interest in such a topic mainly derives from the potential application of heterometallic clusters in catalysis, where the combined action of different metals may enhance catalytic properties [9], but these clusters can also serve as models of the modifications to the substrate that arise at a molecular level. The first reported bimetallic carbonyl cluster, $[\text{FeCo}_3(\text{CO})_{12}]^-$, was synthesized by Chini and co-workers in 1960 [10], and later employed for $[\text{AuL}]^+$ addition reactions (see Table 1).

The authors' ambition is to offer an up-to-date survey of gold-containing transition-metal carbonyl clusters, both homo- and heteroleptic, citing those compounds whose crystal structures have been fully characterized by X-ray analysis, and discussing
