ABSTRACT

We investigated the crystal structure and the martensitic transformation in equiatomic HfPd alloy. The analysis of the crystal structure by electron diffraction and Rietveld refinement using X-ray diffraction data indicates that the space group of the martensitic phase is $Cmcm$, and the lattice parameters are $a = 0.329$ nm, $b = 1.021$ nm, and $c = 0.438$ nm. Martensitic variants are composed of the plate-like morphology of several hundred nm, and the boundaries between the variants have $(021)_{Cmcm}$ twin relations. This $(021)_{Cmcm}$ twin boundary seems to be sharp without ledge and steps. Differential scanning calorimetry measurement indicates that each martensitic transformation temperature is determined to be $M_s = 819$ K, $M_f = 794$ K, $A_s = 928$ K, and $A_f = 954$ K. Based on the dimension change using a thermo-mechanical analyzer, the expansion and shrinkage of the sample occurred with the forward and reverse martensitic transformation, respectively.
