Abstract:

Khademite and rostitite are orthorhombic **minerals** $\text{Al}(\text{SO}_4)_4\text{F} \cdot 5\text{H}_2\text{O}$ and $\text{Al}(\text{SO}_4)_4\text{OH} \cdot 5\text{H}_2\text{O}$, respectively. Libušín is a type locality of rostitite but recent studies have only confirmed the presence of khademite. New electron microprobe analyses of **this mineral** from Libušín revealed a fluorine concentration of 8.12–8.18 wt.%, which is the highest ever found for khademite. The empirical formula is: $\text{Al}_{1.01-1.03}(\text{SO}_4)_{0.98-0.99}(\text{F}_{0.90-1.00}\text{OH}_{0.00-0.10}) \cdot 5\text{H}_2\text{O}$, and lattice parameters for *Pcab* symmetry are $a = 11.182(3)$, $b = 13.051(4)$, $c = 10.889(5)$ Å, $V = 1589.0(7)$ Å³. The intense Raman lines are 990 cm⁻¹ (ν_1); 1081 and 1131 cm⁻¹ (ν_3); 420 and 504 cm⁻¹ (ν_2); 589 and 632 cm⁻¹ (ν_4). Therefore, rostitite has not been proven in Libušín and its existence at other localities is not credibly documented. **The presented data of fluorine khademite are of high importance for geochemical studies and precise discrimination of structurally very similar sulfates. This information can be also used for better understanding of planetary surface and subsurface processes.**

1. Introduction

Aluminum-containing sulfates are common secondary minerals that are generally formed through decomposition of aluminosilicates in the environment rich in sulfate anions. The group includes a number of chemically and structurally diverse minerals, namely aluminite [$\text{Al}_2(\text{SO}_4)(\text{OH})_4 \cdot 7\text{H}_2\text{O}$], meta-aluminite [$\text{Al}_2(\text{SO}_4)(\text{OH})_4 \cdot 5(\text{H}_2\text{O})$], basaluminite [$\text{Al}_4(\text{SO}_4)(\text{OH})_{10} \cdot 5(\text{H}_2\text{O})$], jurbanite [$\text{Al}(\text{SO}_4)(\text{OH}) \cdot 5\text{H}_2\text{O}$], khademite [$\text{Al}(\text{SO}_4)(\text{F},\text{OH}) \cdot 5(\text{H}_2\text{O})$], rostitite [$\text{Al}(\text{SO}_4)(\text{OH},\text{F}) \cdot 5(\text{H}_2\text{O})$], alunogen [$\text{Al}_2(\text{SO}_4)_3 \cdot 17\text{H}_2\text{O}$], and meta-alunogen [$\text{Al}_2(\text{SO}_4)_3 \cdot 13.8\text{H}_2\text{O}$]. Anhydrous aluminum sulfate, millosevichite [$(\text{Al},\text{Fe})_2(\text{SO}_4)_3$], can also be found in natural systems, however, it is very rare. Mixed divalent–trivalent salts (pickeringite-halotrichite series), various alum salts, aluminocopiapite,
