ABSTRACT

The work is dedicated to researching into combustion kinetics and mechanism as well as the stages of the chemical transformations during self-propagating high-temperature synthesis of ZrB_2 -SiC based ceramics. Dependences of the combustion temperature and rate on the initial temperature (T_0) have been studied. It has been shown that the stages of the chemical reactions of ZrB_2 diboride and SiC carbide formation do not change within the range of $T_0 = 298\text{--}700\text{ K}$. The effective activation energy of the combustion process amounted to 170–270 kJ/mol, from which it has been concluded that chemical interaction through the melt plays a leading role. The stages of the chemical transformations in the combustion wave have been studied by dynamic X-ray diffraction. First, ZrB_2 phase forms from Zr-Si melt saturated with boron, and SiC phase is registered later. The SHS method has successfully been used in order to obtain ZrB_2 -SiC composite powders and compact ceramics with a silicon carbide content of 25-75 %. The ceramics are characterized by a residual porosity of 1.5 %, hardness up to 25 GPa, the elastic modulus of $318 \pm 21\text{ GPa}$, elastic recovery of 36 % and thermal conductivity of $54.9\text{ W/(m}\cdot\text{K)}$ at T_{room} .

Keywords: combustion, kinetics, ceramics, zirconium diboride, silicon carbide.

1. Introduction

Zirconium diboride ZrB_2 has a unique complex of properties [1,2]: a high melting temperature ($3245\text{ }^\circ\text{C}$), thermal conductivity ($60\text{--}140\text{ W/(m}\cdot\text{K)}$), hardness ($20\text{--}24\text{ GPa}$), high elastic modulus ($400\text{--}500\text{ GPa}$ and higher), resistance to abrasive wear and aggressive environments.
