## ABSTRACT

The properties of  $\text{CaBi}_4\text{Ti}_4\text{O}_{15}$  (CBT),  $\text{CaBi}_4\text{Ti}_{3.95}\text{Nb}_{0.05}\text{O}_{15}$  (CBTN) and  $\text{CaBi}_4\text{Ti}_{3.95}\text{Nb}_{0.05}\text{O}_{15} + 0.2 \text{ wt\% MnO}_2$  (CBTN–Mn) ferroelectric ceramics with bismuth layer structure were studied. Significant enhancement of piezoelectric coefficient was obtained for CBTN–Mn ceramics ( $d_{33} = 23 \text{ pC/N}$ ), being nearly three times that of CBT counterpart ( $d_{33} = 8 \text{ pC/N}$ ). Together with its high Curie temperature ( $T_c = 790^\circ\text{C}$ ), low dielectric loss ( $\tan\delta = 0.2\%$ ), high resistivity ( $\rho = 4.2 \times 10^6 \Omega \text{ cm}$  at  $500^\circ\text{C}$ ) and good thermal stability up to  $700^\circ\text{C}$ , the CBTN–Mn ceramic is a potential material for high temperature piezoelectric applications.

## 1. Introduction

In last few decades, ferroelectric ceramics with bismuth layer structure have been actively studied for non-volatile random-access memory and high temperature piezoelectric applications, owing to their fatigue-free characteristics and high Curie temperature  $T_c$ , respectively [1–3]. The general formula of bismuth layer-structured ferroelectrics (BLSF) is  $(\text{Bi}_2\text{O}_2)^{2+}(\text{A}_{m-1}\text{B}_m\text{O}_{3m+1})^{2-}$ , which can be described as regular stacking of  $(\text{A}_{m-1}\text{B}_m\text{O}_{3m+1})^{2-}$  pseudo-perovskite blocks, separated by fluorite-like  $(\text{Bi}_2\text{O}_2)^{2+}$  layers along the  $c$  axis [4,5]. The  $(\text{Bi}_2\text{O}_2)^{2+}$  act as insulating paraelectric layers, limiting the spontaneous polarization of BLSF materials in the  $a$ – $b$  plane, i.e., the pseudo-perovskite  $(\text{A}_{m-1}\text{B}_m\text{O}_{3m+1})^{2-}$  blocks. The pseudo-perovskite blocks can offer large possibilities in terms of compositional flexibility, which allow mono-, di-, trivalent element (e.g.,  $\text{Na}^+$ ,  $\text{K}^+$ ,  $\text{Ca}^{2+}$ ,  $\text{Sr}^{2+}$ ,  $\text{Ba}^{2+}$ ,  $\text{Pb}^{2+}$ ,  $\text{Bi}^{3+}$  and  $\text{La}^{3+}$ ), or a mixture of them on the A-site and a transition element (e.g.,  $\text{Fe}^{3+}$ ,  $\text{Cr}^{3+}$ ,  $\text{Ti}^{4+}$ ,  $\text{Nb}^{5+}$ ,  $\text{Ta}^{5+}$ ,  $\text{Mo}^{6+}$  and  $\text{W}^{6+}$ ) on the B-site [6]. The number of  $[\text{BO}_6]$  octahedra in the pseudo-perovskite blocks  $m$  (basically from 1 to 6) strongly affects the dielectric and ferroelectric properties of BLSF, because the spontaneous polarization arises from different modes of  $[\text{BO}_6]$  octahedral rotation, where the displacement of the ions on the B-site dominates the polarization component in the  $a$ – $b$  plane of the pseudo-perovskite layers.

$\text{CaBi}_4\text{Ti}_4\text{O}_{15}$  (CBT) belongs to the family of BLSF with  $m = 4$ , where  $\text{Ca}^{2+}$  and  $\text{Bi}^{3+}$  located at A-site, while  $\text{Ti}^{4+}$  occupied the B-site of the pseudo-perovskite blocks. Compared to other extensively studied BLSF ceramics with  $m = 4$ , such as  $\text{Na}_{0.5}\text{Bi}_{4.5}\text{Ti}_4\text{O}_{15}$  ( $T_c = 668^\circ\text{C}$ ,  $d_{33} = 17 \text{ pC/N}$ ) [7] and  $\text{K}_{0.5}\text{Bi}_{4.5}\text{Ti}_4\text{O}_{15}$  ( $T_c = 555^\circ\text{C}$ ,  $d_{33} = 21.2 \text{ pC/N}$ ) [8], CBT was reported to possess higher Curie temperature ( $T_c = 790^\circ\text{C}$ ) but much lower piezoelectric coefficient ( $d_{33} = 8 \text{ pC/N}$ ) [9]. It was reported that  $(\text{MCE})^{2+}$  ( $\text{M} = \text{Li}, \text{Na}, \text{K}$ ) doped CBT ceramics can effectively enhance the piezoelectric coefficient up to  $20 \text{ pC/N}$  without sacrificing the Curie temperature [10,11]. However, the B-site modification of CBT ceramics, being expected to possess substantially increased  $d_{33}$  ( $>20 \text{ pC/N}$ ), has not yet been reported, which is the topic of this research.

The structure and properties of B-site Nb-doped and Nb/Mn co-doped CBT ceramics were investigated and compared with pure CBT counterpart. Enhanced piezoelectric coefficient ( $d_{33} = 23 \text{ pC/N}$ ) was obtained in Nb/Mn co-doped CBT ceramics. Of particular importance is that the B-site modified CBT ceramics do not contain the alkali metals, such as in  $\text{Na}_{0.5}\text{Bi}_{4.5}\text{Ti}_4\text{O}_{15}$ ,  $\text{K}_{0.5}\text{Bi}_{4.5}\text{Ti}_4\text{O}_{15}$ , and A-site  $(\text{MCE})^{2+}$  ( $\text{M} = \text{Li}, \text{Na}, \text{K}$ ) doped CBT, making the ceramic fabrication process easier.

## 2. Experimental procedures

Ceramic samples of  $\text{CaBi}_4\text{Ti}_4\text{O}_{15}$  (CBT),  $\text{CaBi}_4\text{Ti}_{3.95}\text{Nb}_{0.05}\text{O}_{15}$  (CBTN), and  $\text{CaBi}_4\text{Ti}_{3.95}\text{Nb}_{0.05}\text{O}_{15} + 0.2 \text{ wt\% MnO}_2$  (CBTN–Mn) were prepared by the solid state reaction method. Reagent-grade  $\text{CaCO}_3$  (99.9%),  $\text{Bi}_2\text{O}_3$  (99.9%),  $\text{TiO}_2$  (99.9%),  $\text{Nb}_2\text{O}_5$  (99.5%), and  $\text{MnO}_2$  (99.9%) were selected as the starting raw materials. The raw

powders were mixed by ball milling with ethanol for 24 h, then dried and calcined at 800 °C for 2 h. A small amount of Rhoplex binder (1.0 wt%) was added in the calcined powders and milled again, dried and pressed into pellets. After the binder burn-out, the pellets were cold isostatic pressed and subsequently sintered at 1075–1175 °C for 2 h in air. The phase structure was determined by X-ray diffraction (XRD: X'Pert Pro PANalytical, CuK $\alpha$  radiation), which was analyzed by X'Pert HighScore software. The microstructure features of the polished and thermally-etched surfaces, as well as the fractured surfaces of the sintered ceramics were characterized by the field emission scanning electron microscopy (FE-SEM, JSM-5610LV; JEOL, Japan).

The obtained samples were parallel polished and painted with silver paste on both sides, then fired at 750 °C to form the electrodes. The electrical resistivity was calculated from the resistance, which was measured using a source meter (Keithley 2410C) by applying 100 V on the samples. The temperature dependence of the dielectric constant and loss at 100 kHz was determined by an LCR meter (HP4194A, Hewlett-Packard, CA) with the temperature increasing from 30 to 850 °C. For the piezoelectric
