Abstract

CuO thin film/TiO₂ nanotubes heterostructures were fabricated to investigate the effect of p-n heterojunction on sensing properties. TiO₂ nanotubes were synthesized via anodization of Ti foil. Then, CuO thin film was covered on the nanotubes by oxidation of thermally evaporated Cu layer. For comparison, sensor devices those are composed of only CuO thin film and composed of TiO₂ nanotubes have been also fabricated. The heterostructure was characterized by X-ray diffraction (XRD), scanning electron microscopy (SEM) and energy-dispersive X-ray (EDX) spectroscopy. Fabricated sensor devices were exposed to H₂, ethanol, acetone, chloroform and NO₂ gases at different operation temperatures. Experimental results showed that the heterostructure sensor has better performance toward H₂ in sensing with low operation temperature, low detection limit and high sensor response compared to TiO₂ nanotubes and CuO thin film. Moreover, the formation of heterostructure not only increased response toward H₂ but also dramatically decreased response toward VOCs and NO₂. These improved sensing properties are attributed to the heterojunction between CuO thin film and TiO₂ nanotubes.

1. Introduction

Metal-oxides (MOx) are pre-eminent candidates in applications of gas sensor such as medical use, air quality monitoring, food industry and detection of hazardous gases due to their high sensitivity, low cost, easy fabrication and adaptability [1-5]. Among these MOx materials, TiO₂, is one of the most widely used n-type semiconductors[3]. TiO₂ has also been studied for many other applications in medicine and electronics such as transistors, solar cells, and batteries [6-9]. In the last decades, nanostructures of TiO₂ have been widely studied in the field of gas sensors due to their high surface-to-volume ratio, extension of the surface charge region, excellent chemical and thermal stability, faster response and recovery time [6, 10-14]. It was reported that 1D TiO₂ nanostructures show promising sensing performance toward H₂ [15, 16], ethanol [17], acetone [18], CO [19] and NO₂ [20] at working temperatures between 300-600°C.

In recent years, due to the strong demand for better sensor properties for almost all sensor applications, studies have focused on different heterostructures based on metal-oxides
