**Abstract**

In the present work,  $\text{Ba Zr}_{0.1}\text{Ce}_{0.7}\text{Y}_{0.2}\text{O}_{3-\delta}$  (BZCY7)- $(\text{Li/Na})_2\text{CO}_3$  composite electrolytes fabricated by infiltration of molten carbonate phase into porous based BZCY7 electrolytes, prepared by using different types of pore formers including graphite, active carbon and starch. The effect of pore formers sizes, morphologies and their amounts, was investigated on the volume fraction of porosities, which can be created during sintering of BZCY7 electrolytes and on the morphologies of the formed porosities. The effect of created pores morphologies, sizes, their volume fractions and also infiltration's temperature and time on the degree of infiltration and electrical conductivity of the fabricated composite electrolytes were also studied. The results proved that by using 20 wt% of each type of the used pore formers, same amount of porosities in the range of 40 to 45 vol.% would be created during sintering of BZCY7 compound at 1400 °C for 5 h. By using pore formers more than 20 wt%, the amount of created porosities did not change or just increased a little and soon after it nearly became saturated. Optimum temperature and time for infiltration of melt carbonate phase was determined in the range of 530 to 570 °C for
