## Abstract

Micro-scale strain distribution, an integrated response of microstructural parameters, is crucial to designing the microstructure of two-phase titanium alloys. In this paper, a microstructure-based finite element model is used to analyze the effect of microstructural parameters, such as volume fraction and distribution of primary  $\alpha$  ( $\alpha_p$ ), yield stress of transformed  $\beta$  ( $\beta_t$ ) on micro-scale strain distribution of two-phase titanium alloys. Strain distribution factor (SDF) is proposed to quantitatively characterize the strain distribution. It is found that with increasing SDF the homogeneity of strain distribution increases. Decreasing yield stress of  $\beta_t$  and increasing volume fraction of  $\alpha_p$  will increase SDF, whereas directional distribution of  $\alpha_p$  will significantly decrease SDF. An SDF window for different  $\alpha_p$  volume fractions and  $\beta_t$  yield stress is constructed, guiding the microstructural design of two-phase titanium alloy.

Keywords: Strain distribution, Microstructure, Metals and alloys, Simulation and modelling

## 1. Introduction

Two-phase titanium alloys have a unique microstructure containing soft primary  $\alpha$  ( $\alpha_p$ ) and hard transformed  $\beta$  matrix ( $\beta_t$ ). The combined effects of  $\alpha_p$  and  $\beta_t$  with different volume fractions, distributions and mechanical properties can give titanium alloys high tensile strength or high ductility [1-3]. As a result, microstructural design can provide titanium alloys with excellent properties. Therefore, titanium alloys can meet the high service requirement widely used in the aviation and aerospace industries [4-6].

To design the microstructure of titanium alloys, Kar et al. [7] analyzed the influence of microstructure on the mechanical properties of Ti-5553, and pointed out that with increasing volume fraction of  $\alpha_p$  ( $V_{\alpha_p}$ ), the yield strength of the alloy decreases. Wang et al. [8] produced a series of microstructures of TG6 titanium alloy with  $V_{\alpha_p}$  of 15.1% to 40.5% and thickness of lamellar  $\alpha$  of 0.4
