8 **Abstract**

9 A theoretical and experimental study was carried out on performance of a Tubular
10 Solar Still (TSS) under vacuum operation condition, based on which a modified
11 model was proposed. Theoretical analysis shows that a vacuum operation pressure
12 augments the concentration differential of humid vapour around the trough and that
13 around the condensation surface, intensifying the diffusion and natural convection of
14 vapour in the cavity. It is further indicated that as the operation pressure approximates
15 the saturation pressure of the saline water, buoyancy force due to mass transfer would
16 surpass that from thermal diffusion, and dominate vapour transportation process in the
17 still. The proposed model for predicting the freshwater yield adopted the diffusion
18 rule of binary mixture in the calculation of the mass transfer coefficient. It has a
19 deviation of -3% - 11% against the current experimental results and was further
20 verified by an independent dataset. Upon that the performance of current TSS under
21 vacuum running condition was evaluated with the help of the model. In view of the
22 efficiency in energy utilization, the evaluation results show that the energy utilization
23 efficiency of the system has an increase over 80% compared with that under normal
24 operating pressure condition.

25 **Keywords:** Dynamic energy model; Tubular Solar Still; Solar desalination; Vacuum
26 pressure; Mass transfer
