8 **Abstract:** This paper presents a strategic bidding model for several price-taker plug-in electric
9 vehicle aggregators sharing the same distribution network that participate in both day-ahead
10 energy and ancillary services (up/down-regulation reserve) markets. Since the strategic feasible
11 space of an aggregator depends on the actions of the other aggregators due to the limited capacity
12 of the existing feeders, the proposed problem forms a generalized Nash equilibrium problem. The
13 aggregators' objective is considered to be the cost of purchased energy from the day-ahead and
14 real-time market minus the revenue from the day-ahead regulation market. A hybrid
15 stochastic/robust optimization model is employed to deal with different uncertainties an aggregator
16 faces in the bidding strategy problem. These uncertainties include day-ahead energy prices, day-
17 ahead up/down-regulation prices, and real-time energy prices. Day-ahead prices are modeled by
18 different scenarios, while real-time prices are represented by the confidence bounds. Results of a
19 case study are shown to demonstrate the applicability and tractability of the proposed model.
