8           **Abstract**

9           Urban ecological infrastructures (UEIs; e.g., parks, beaches, rivers, forests, and woodlands)  
10          provide important ecosystem services (ESes) to urban ecosystems. Understanding the covariance  
11          of multiple ESes and disservices and their associations with social economic factors is a  
12          precondition of ecosystem management. Previous studies have mainly focused on ESes and  
13          tradeoffs among multiple ESes, whereas disservices and their associations with ESes have seldom  
14          been addressed. In this study, we took public urban parks, an important component of UEIs as well  
15          as the basic unit for management, as a case study and explored the ESes and disservices of  
16          different types of parks and the delivery of ESes to different social economic strata based on 187  
17          plot inventory data. The results showed that the actual dominant ESes of four types of parks  
18          differed from both the expectations of planners and the demands of residents. Positive correlations  
19          existed among ESes and disservices (e.g. bio-emissions and air pollution reduction). Population  
20          density was positively related with several ESes; Distance to urban center was negatively  
21          associated with C storage, bio-emissions, and aggregative ES indicators; Wealthy areas had better  
22          performance in terms of C storage and aggregative ES indicators. Major challenges for the four  
23          types of parks and measures to coordinate ESes and disservices are discussed. Multiple  
24          stakeholder involvement, ES provision for low income populations, and the protection of parks in  
25          peri-urban and central urban areas are suggested.

26          **Keywords:** urban ecological infrastructure, ecosystem service, green space, disservice

27          **1 Introduction**

28          The world is experiencing rapid urbanization. Between 1950 and 2005, the level of  
29          urbanization increased from 29% to 49%, while global carbon (C) emissions from fossil-fuel  
30          burning increased by almost 500% (UN-Habitat 2016). Urban ecosystems account for more than  
31          75% of the global resource consumption and contribute to 80% of the C emissions (UN, 2012). In  
32          addition, the large-scale land use conversion from peri-urban forests, farmlands, and wetlands to  
33          built-up areas has resulted in a critical loss of ecosystem services (ESes) at the local to global  
34          scales (Breuste et al., 2015; Li et al., 2016; Seto et al., 2012). The concept of urban ecological  
35          infrastructures (UEIs) has been developed within the last three decades and commonly refers to  
36          the connective matrices of green space, wetlands, rivers, pervious surfaces, and traditional gray  
37          infrastructures (Breuste et al., 2015; Li et al., 2016). UEIs are the main carrier of ecosystem  
38          services in urban ecosystems and are closely related to the quality of life of urban residents  
39          (Breuste et al., 2015). UEIs include a comprehensive set of functions: water supply and recycling,  
40          soil fertility and biodiversity maintenance, materials decomposition and waste regeneration, and
