## 6 Abstract

7 Stress sensitivity parameters of a fracture are often tested under compression on both  
8 sides of the fractured medium, which is considered as an elastic solid. However, the  
9 elastic solid assumption will fail when two fracture surfaces, if applied to tensile  
10 stresses, are out of contact. In such cases, effective stress in the fracture is zero and  
11 the change of fracture aperture is not determined by the fracture itself, but by the  
12 deformation of the matrix and the overall deformation of the fractured region. This  
13 paper proposed a zero-stress model that is applicable after the failure of elastic  
14 fracture model as described above. The model analyzes the deformation mechanism  
15 of fractures and derives a new equation that can be used to describe the aperture and  
16 permeability behavior of a fractured medium under the condition of zero stress. The  
17 model is derived for different geometric shapes of fractured region under hydrostatic  
18 pressures. The model equations can be used to calculate aperture and permeability  
19 changes caused by the production of oil and gas from a reservoir as well as the  
20 injection of water or gases for EOR. Sensitivity analysis of the model found that both  
21 shape factor of the fractured region and elastic modulus of the surrounding rocks have  
22 a significant impact on the outcome of the aperture and permeability forecast as a  
23 function of changing pore pressure. The permeability model can also be used in  
24 reservoir engineering analysis and reservoir numerical simulation. The new model is  
25 joined with the traditional elastic model to better describe the deformation process of  
26 fractures.

27 Keywords: oil and gas reservoir, zero-stress model, high dip fracture, fracture aperture,  
28 fracture permeability

## 29 1. Introduction

30 Fractures are crucial to fractured reservoirs because they are the main channels or  
31 pathways for fluids to flow. Matrix blocks are often tight and poorly permeable in  
32 such reservoirs. Crudes stored in the pores of matrix firstly flow into the fracture and  
33 finally find their way to the wellbore.

34 Flow rate of fluids through fractures is directly affected by fracture permeability,  
35 which is a unique function of fracture aperture (Iwai 1976). Many laboratory tests  
36 have confirmed that the fracture permeability or fracture aperture is pressure sensitive  
37 (Rutqvist 2003, Guo et al. 2013, Huo et al. 2014). Bandis (1980) and Barton (1985)  
38 conducted a large body of experiments and proposed a constitutive model or the
