7 **Abstract**

8 Model developments for transient analysis of fractured horizontal wells have gained
9 tremendous attention in shale reservoirs, especially, during the flowback period.
10 However, the existing models so far have rarely considered two-phase flow and
11 complex fracture networks. To improve this situation, in this work, we present a
12 comprehensively semianalytical two-phase flow model. Two fluids simultaneously
13 flow in the matrix and fracture networks. By iteratively correcting the relative
14 permeability to the phases, we incorporate the two-phase flow into fracture model.
15 Complex fracture networks with arbitrary geometries are described and the fluid flow
16 interplays at fracture intersections are eliminated by mass balance equation. The
17 model solution is obtained by using Laplace transform inversion, and it is verified by
18 performing a case study with numerical simulators. Our results show that there exist
19 two distinct flow regimes: fluid feed and pseudo-boundary dominated flow (PBDF),
20 which is generated by the permeability contrast between fracture networks and matrix.
21 We also investigate the impacts of some key reservoir and fracture properties on the
22 characteristics of the two-phase productivity index. Results indicate that the
23 two-phase productivity index increases with an increase in initial water saturation.
24 Furthermore, it is found that during the PBDF, different fracture-network parameters
25 have various constant productivity indexes, providing an efficient tool to characterize
26 the fracture networks. Based on that, we apply the model to estimate the fracture
27 networks of a well in CJ formation from China with flowback data and micro seismic
28 data, which provides an efficient technique to estimate the fracture parameters during
29 the flowback period.
