9 ABSTRACT:

10  
11 We present an alternative approach to making counting measurements of radioactivity  
12 which offers probabilistic interpretations of the measurements. Unlike the approach in the  
13 current international standard (ISO-11929), our approach, which uses an assumed prior  
14 probability distribution of the true amount in the sample, is able to answer the question of  
15 interest for most users of the standard: “what is the probability distribution of the true amount  
16 in the sample, given the data?” The final interpretation of the measurement requires  
17 information not necessarily available at the measurement stage. However, we provide an  
18 analytical formula for what we term the “measurement strength” that depends only on  
19 measurement-stage count quantities. We show that, when the sources are rare, the posterior  
20 odds that the sample true value exceeds  $\varepsilon$  are the measurement strength times the prior odds,  
21 independently of  $\varepsilon$ , the prior odds, and the distribution of the calibration coefficient. We  
22 recommend that the measurement lab immediately follow-up on unusually high samples  
23 using an “action threshold” on the measurement strength which is similar to the decision  
24 threshold recommended by the current standard. We further recommend that the  
25 measurement lab perform large background studies in order to characterize non constancy of  
26 background, including possible time correlation of background.
