Soliton solutions

ABSTRACT

In this work, we investigate the $(2 + 1)$ -dimensional B-type Kadomtsev–Petviashvili (BKP) equation, which can be used to describe weakly dispersive waves propagating in the quasi media and fluid mechanics. We construct the more general lump solutions, localized in all directions in space, with more arbitrary autocephalous parameters. By considering a stripe soliton generated completely by lump solution, a lumpoff solution is presented. Its lump part is cut by soliton part before or after a specific time, with a specific divergence relationship. Furthermore, combining a pair of stripe solitons, we obtain the special rogue waves when lump solution is cut by double solitons. Our results show that the emerging time and place of the rogue waves can be caught through tracking the moving path of lump solution, and confirming when and where it happens a collision with the visible soliton. Finally, some graphic analysis are discussed to understand the propagation phenomena of these solutions.

1. Introduction

Nonlinear evolution equations (NLEEs) have a widespread application in the field of mathematical physics and engineering, such as fluid mechanics, plasma physics and optical fibers, etc. Finding exact solutions of NLEEs is one of the hot topics in this field. More and more researchers are interested in study this topic. Soliton solution, as a special exact solution, has an important position in the NLEEs. Over the development of the past decade, a number of methods have been presented to solve NLEEs, such as inverse scattering method [1], Hirota bilinear method [2], Darboux transformation (DT) [3] and Lie group method [4], etc. Recently, the researches of lump waves have attracted many attentions. As one kind of rogue waves with rational form, lump solution is localized in all directions in the space and appear in many physical phenomena, such as optical fibers, super-fluids and Bose–Einstein condensates [5–10]. Due to its important physical significance, the lump solution was first discovered in [11]. By employing Hirota bilinear method, a new direct method to get the lump solutions of KP equation was provided in [12]. It is a beautiful and wonderful method to seek lump solutions for nonlinear evolution equations. In terms of the direct method, the lump solutions for a lot of integrable equations have been derived, such as p-gKP equation,

Yajima–Oikawa system [13–15], etc. Furthermore, the interaction solutions between lump waves and stripe solitons have been frequently reported in current research. There are many works to study the interaction solutions for the generalized KP equation [16], KP equation [17] and Ito equation [18], etc. These results indicate that the interaction solutions between the lump waves and a pair of stripe solitons could create the rogue waves at a special time.

In this work, we will consider the following $(2 + 1)$ -dimensional B-type Kadomtsev–Petviashvili (BKP) equation [19]

$$u_t + u_{xxxxx} - 5 \left(u_{xxy} + \int u_{yy} d_x \right) + 15 \left(u_x u_{xx} + u u_{xxx} - u u_y - u_x \int u_y d_x \right) + 45 u^2 u_x = 0, \quad (1.1)$$

where $u = u(x, y, t)$ is a analytic function with scaled spatial coordinates (x, y) and temporal coordinate t , the subscripts mean partial derivatives, and \int is integration operator. The BKP equation, as a subclass of the KP hierarchy, can be used to describe weakly dispersive waves propagating in the quasi media and fluid mechanics. The multiple soliton solutions were established for Eq. (1.1) based on the simplified form of the Hirota method [20], and its periodic wave solutions with asymptotic behaviors were derived via using Riemann theta function in [21]. The soliton solutions, quasi-periodic wave solutions with their relations for the BKP equation

1 were also reported in [22]. By using the extended homoclinic test
2 method, rogue waves and homoclinic breather waves were pro-
3 vided in [23].

4 However, the main purpose of this work is to study the more
5 general lump solutions, lumpoff solutions and predictable rogue
6 wave solutions of the BKP equation (1.1) by using the symbolic
7 calculation methods [24–50]. We first construct a general form of the
8 lump solutions and analyze their moving path. Then, the lumpoff
9 solutions, whose lump part can be cut by the soliton part during
10 a specific time, are presented. The characteristics of lumpoff waves
11 are that the soliton part is produced completely by the lump part.
12 Moreover, when the lump waves are cut by a pair of stripe solitons
13 produced by lump waves, a special rogue waves are generated. It
14 is interesting that the special rogue waves can be forecasted by
15 tracking where and when they emerge.

16 The outline of this work is as follows. In section 2, by con-
17 structing the general form of the lump solutions, we derive the
18 general lump waves with the help of bilinear form for Eq. (1.1). In
19 section 3, the lumpoff solutions of the equation are provided. In
20 section 4, we obtain the special rogue solutions and indicate that
21 they have predictability. Finally, some conclusions are given in the
22 last section.

23
24 **2. General lump solutions for BKP equation**

25 First of all, we introduce a variable transformation

26
$$u = 2(\ln f)_{xx}, \tag{2.1}$$

27 where $f = f(x, y, t)$ is a function to be determined later. Substitu-
28 tion of (2.1) into (1.1) results in the following Hirota bilinear form
29 for the BKP equation (1.1)

30
$$\left(D_x^6 - 5D_x^3 D_y - 5D_y^2 + D_x D_t \right) f \cdot f = 0, \tag{2.2}$$

31 with the D -operator defined by

32
$$D_x^l D_y^n D_t^m (f \cdot g) = \left(\frac{\partial}{\partial x} - \frac{\partial}{\partial x'} \right)^l \left(\frac{\partial}{\partial y} - \frac{\partial}{\partial y'} \right)^n \left(\frac{\partial}{\partial t} - \frac{\partial}{\partial t'} \right)^m$$

33
$$\times f(x, y, t) \cdot g(x', y', t') \Big|_{x=x', y=y', t=t'}. \tag{2.3}$$

34 The bilinear equation (2.2) has the following equivalent formula

35
$$2f_{6x}f - 12f_{5x}f_x + 30f_{4x}f_{xx} - 20f_{3x}^2 - 10f_{xxy}f + 30f_{xy}f_x$$

36
$$- 30f_{xy}f_{xx} + 10f_yf_{3x} - 10f_{yy}f + 10f_y^2 + 2f_{xt}f - 2f_xf_t = 0. \tag{2.4}$$

37 If the solution f of above equation (2.4) is positive, the solution
38 u defined by BKP equation (1.1) will be analytical based on the
39 transformation in (2.1) (cf. [14]).

40 To get the single lump solution of BKP equation, we suppose a
41 general quadratic function given by

42
$$f = x^T Mx + f_0, \tag{2.5}$$

43 with

44
$$M = \begin{pmatrix} m_{00} & m_{01} & m_{02} & m_{03} \\ m_{10} & m_{11} & m_{12} & m_{13} \\ m_{20} & m_{21} & m_{22} & m_{23} \\ m_{30} & m_{31} & m_{32} & m_{33} \end{pmatrix}, \quad x^T = (x_0, x_1, x_2, x_3), \tag{2.6}$$

45 where $f_0 \in R$ is a positive constant, $M \in R^{4 \times 4}$ is a symmetric ma-
46 trix, and $x^T \in R^4$ is a column vector and denotes the variables of
47 function f . Letting $x_0 = 1, x_1 = x, x_2 = y, x_3 = t$, we can rewrite f
48 as

49
$$f = \sum_{i,j=0}^3 m_{ij}x_i x_j + f_0 = m_{11}x^2 + m_{22}y^2 + m_{33}t^2 + 2m_{12}xy$$

50
$$+ 2m_{13}xt + 2m_{23}yt + 2m_{01}x + 2m_{02}y + 2m_{03}t$$

51
$$+ m_{00} + f_0. \tag{2.7}$$

52 According to the transformation $u = 2(\ln f)_{xx}$, it is not hard to
53 see that f must be positive. Therefore, $\sum_{i,j=0}^3 m_{ij}x_i x_j$ should be
54 non-negative. In order to make it, we redefine m_{ij} as follows

55
$$m_{ij} = \vec{P}_i \cdot \vec{P}_j = \sum_{k=1}^n P_{ik} P_{jk}, \tag{2.8}$$

56 where

57
$$\vec{P}_1 = \vec{a} = (a_1, a_2, \dots, a_n), \quad \vec{P}_2 = \vec{b} = (b_1, b_2, \dots, b_n),$$

58
$$\vec{P}_3 = \vec{c} = (c_1, c_2, \dots, c_n), \quad \vec{P}_0 = \vec{\lambda} = (\lambda_1, \lambda_2, \dots, \lambda_n), \tag{2.9}$$

59 are n dimension vectors and a_k, b_k, c_k, λ_k ($k = 1, 2, \dots, n$) are real
60 scalar parameters to be known later. Letting $\vec{\chi} = \sum_{i=0}^3 x_i \vec{P}_i$, we
61 have

62
$$\sum_{i,j=0}^3 m_{ij}x_i x_j = \vec{\chi} \cdot \vec{\chi} = \sum_{k=1}^n \chi_k^2 \geq 0.$$

63 Thus f is always positive with m_{ij} defined by (2.8).

64 Substituting Eqs. (2.7)–(2.9) into equation (2.4) and collecting
65 all the coefficients about x, y, t , we can obtain ten determining
66 equations for m_{ij} . Solving these resulting equations based on (2.8),
67 we can easily find the following constraints

68
$$c_k = \frac{-5(m_{22}a_k - 2m_{12}b_k)}{m_{11}},$$

69
$$f_0 = -m_{00} + \frac{m_{01}^2 m_{22} - 2m_{01}m_{02}m_{12} + m_{02}^2 m_{11}}{m_{11}m_{22} - m_{12}^2}$$

70
$$- \frac{3m_{11}^2 m_{12}}{m_{11}m_{22} - m_{12}^2}. \tag{2.10}$$

71 Because the dimension n of the vectors \vec{P}_i are undetermined, one
72 can see that Eq. (2.7) with (2.8) should include a large number
73 of parameters. Referring to the results presented in [51], we know
74 that it is a more right choice for $n = 3$ to generate a more gener-
75 al lump solutions of Eq. (1.1). Therefore, taking $n = 3$, we rewrite
76 constraint conditions as

77
$$c_1 = \frac{5[a_1(b_1^2 - b_2^2 - b_3^2) + 2b_1(a_2b_2 + a_3b_3)]}{a_1^2 + a_2^2 + a_3^2},$$

78
$$c_2 = \frac{5[a_2(b_2^2 - b_1^2 - b_3^2) + 2b_2(a_1b_1 + a_3b_3)]}{a_1^2 + a_2^2 + a_3^2},$$

79
$$c_3 = \frac{5[a_3(b_3^2 - b_1^2 - b_2^2) + 2b_3(a_1b_1 + a_2b_2)]}{a_1^2 + a_2^2 + a_3^2},$$

80
$$f_0 = -\frac{[\lambda_1(a_2b_3 - a_3b_2) + \lambda_2(a_3b_1 - a_1b_3) + \lambda_3(a_1b_2 - a_2b_1)]^2}{(a_1b_2 - a_2b_1)^2 + (a_2b_3 - a_3b_2)^2 + (a_1b_3 - a_3b_1)^2}$$

81
$$- \frac{3(a_1^2 + a_2^2 + a_3^2)(a_1b_1 + a_2b_2 + a_3b_3)}{(a_1b_2 - a_2b_1)^2 + (a_2b_3 - a_3b_2)^2 + (a_1b_3 - a_3b_1)^2}, \tag{2.11}$$

82 where a_k, b_k, λ_k ($k = 1, 2, 3$) are all arbitrary parameters.

83 Based on above analysis, the general lump solution u of BKP
84 equation (1.1) can be expressed by
