## ABSTRACT

**Background:** Alzheimer's disease (AD) is the most common neurodegenerative disorder which is characterized by the deposits of intra-cellular tau protein and extra-cellular amyloid- $\beta$  (A $\beta$ ) peptides in the human brain. Understanding the mechanism of protein aggregation and finding compounds that are capable of inhibiting its aggregation is considered to be highly important for disease therapy.

**Methods:** We used an *in vitro* High-Throughput Screening for the identification of potent inhibitors of tau aggregation using a proxy model; a highly aggregation-prone hexapeptide fragment <sup>306</sup>VQIVYK<sup>311</sup> derived from tau. Using ThS fluorescence assay we screened a library of 2,401 FDA approved, bio-active and natural compounds in attempt to find molecules which can efficiently modulate tau aggregation.

**Results:** Among the screened compounds, palmatine chloride (PC) alkaloid was able to dramatically reduce the aggregation propensity of PHF6 at sub-molar concentrations. PC was also able to disassemble preformed aggregates of PHF6 and reduce the amyloid content in a dose-dependent manner. Insights obtained from MD simulation showed that PC interacted with the key residues of PHF6 responsible for  $\beta$ -sheet formation, which could likely be the mechanism of inhibition and disassembly. Furthermore, PC could effectively inhibit the aggregation of full-length tau and disassemble preformed aggregates.

**Conclusions:** We found that PC possesses “dual functionality” towards PHF6 and full-length tau, i.e. inhibit their aggregation and disassemble pre-formed fibrils.

**General significance:** The “dual functionality” of PC is valuable as a disease modifying strategy for AD, and other tauopathies, by inhibiting their progress and reducing the effect of fibrils already present in the brain.
