*Keywords:* Riemannian manifolds Fully nonlinear parabolic equations First initial–boundary value problem *a priori* estimates

## 1. Introduction

In this paper, we study the Hessian equations of parabolic type of the form

$$
f(\lambda(\nabla^2 u + \chi), -u_t) = \psi(x, t)
$$
\n(1.1)

in  $M_T = M \times (0,T] \subset M \times \mathbb{R}$  satisfying the boundary condition

$$
u = \varphi, \quad \text{on } \mathcal{P}M_T,\tag{1.2}
$$

where (*M, g*) is a compact Riemannian manifold of dimension *n* ≥ 2 with smooth boundary *∂M* and  $\overline{M}$  :=  $M \cup \partial M$ ,  $\mathcal{P}M_T = BM_T \cup SM_T$  is the parabolic boundary of  $M_T$  with  $BM_T = M \times \{0\}$  and  $SM_T = \partial M \times [0, T]$ , *f* is a symmetric smooth function of  $n+1$  variables,  $\nabla^2 u$  denotes the Hessian of  $u(x, t)$ with respect to  $x \in M$ ,  $u_t = \frac{\partial u}{\partial t}$  is the derivative of  $u(x, t)$  with respect to  $t \in [0, T]$ ,  $\chi$  is a smooth  $(0, 2)$ tensor on  $\overline{M}$  and  $\lambda(\nabla^2 u + \chi) = (\lambda_1, \ldots, \lambda_n)$  denotes the eigenvalues of  $\nabla^2 u + \chi$  with respect to the metric *g*.

In this paper, we are concerned with the first initial–boundary value problem for a class of fully nonlinear parabolic equations on Riemannian manifolds. As usual, the establishment of the *a priori*  $C^2$  estimates is our main part. Based on these estimates, the existence of classical solutions is proved under conditions which are nearly optimal.

We assume f to be defined in an open convex cone  $\Gamma \subset \mathbb{R}^{n+1}$  with vertex at the origin satisfying

$$
\varGamma_{n+1}\equiv\{\lambda\in\mathbb{R}^{n+1}:\text{ each component }\lambda_i>0,\;1\leq i\leq n+1\}\subseteq\varGamma\neq\mathbb{R}^{n+1}
$$

and furthermore,  $\Gamma$  is invariant under interchange of any two  $\lambda_i$ , i.e. it is symmetric.

In this work,  $f$  is assumed to satisfy the following structural conditions as in  $[3]$  (see  $[9]$  also):

$$
f_i \equiv \frac{\partial f}{\partial \lambda_i} > 0 \text{ in } \Gamma, \quad 1 \le i \le n+1,
$$
\n(1.3)

<span id="page-1-0"></span> $f$  is concave in  $\Gamma$  (1.4)

and

$$
\delta_{\psi,f} \equiv \inf_{M_T} \psi - \sup_{\partial \Gamma} f > 0, \quad \text{where } \sup_{\partial \Gamma} f \equiv \sup_{\lambda_0 \in \partial \Gamma} \limsup_{\lambda \to \lambda_0} f(\lambda). \tag{1.5}
$$

In this work we are interested in the existence of classical solutions to  $(1.1)$ – $(1.2)$ . Recent research on the Hessian equations of elliptic type (see  $[9,7]$  $[9,7]$ ):

$$
f(\lambda(\nabla^2 u + \chi)) = \psi(x) \tag{1.6}
$$

provides some ideas to deal with our Eq. [\(1.1\)](#page-0-1) under nearly minimal restrictions on *f*.

The most typical examples of *f* satisfying  $(1.3)$ – $(1.5)$  are  $f = \sigma_k^{1/k}$  $\int_{k}^{1/k}$  and  $f = (\sigma_k/\sigma_l)^{1/(k-l)}$ ,  $1 \leq l < k \leq$  $n + 1$ , defined in the Gårding cone

$$
\Gamma_k = \{ \lambda \in \mathbb{R}^{n+1} : \sigma_j(\lambda) > 0, \ j = 1, \dots, k \},
$$

where  $\sigma_k$  are the elementary symmetric functions

$$
\sigma_k(\lambda) = \sum_{i_1 < \dots < i_k} \lambda_{i_1} \dots \lambda_{i_k}, \quad k = 1, \dots, n+1.
$$

When  $f = \sigma_{n+1}^{1/(n+1)}$ , Eq. [\(1.1\)](#page-0-1) can be written as the parabolic Monge–Ampère equation:

<span id="page-1-1"></span>
$$
-u_t \det(\nabla^2 u + \chi) = \psi^{n+1},\tag{1.7}
$$

which was introduced by Krylov in [\[19\]](#page--1-3) when  $\chi = 0$  in Euclidean space. Instead of the determinant in [\(1.7\),](#page-1-1) Ren [\[25\]](#page--1-4) studied equations of the form

$$
-u_t f(\lambda(\nabla^2 u)) = \psi(x, t). \tag{1.8}
$$

Our interest to study [\(1.1\)](#page-0-1) is from their natural connection to the deformation of surfaces by some curvature functions. For example, Eq. [\(1.7\)](#page-1-1) plays a key role in the study of contraction of surfaces by Gauss–Kronecker curvature (see Firey [\[5\]](#page--1-5) and Tso [\[28\]](#page--1-6)). For the study of more general curvature flows, the reader is referred to [\[1](#page--1-7)[,2,](#page--1-8)[14,](#page--1-9)[24\]](#page--1-10) and their references. [\(1.7\)](#page-1-1) is also relevant to a maximum principle for parabolic equations (see Tso [\[29\]](#page--1-11)).

In [\[23\]](#page--1-12), Lieberman studied the first initial–boundary value problem of Eq. [\(1.1\)](#page-0-1) when  $\chi \equiv 0$  and  $\psi$  may depend on *u* and  $\nabla u$  in a bounded domain  $\Omega \subset \mathbb{R}^{n+1}$  under various conditions. Jiao and Sui [\[18\]](#page--1-13) considered parabolic Hessian equations of the form

<span id="page-1-2"></span>
$$
f(\lambda(\nabla^2 u + \chi)) - u_t = \psi(x, t) \tag{1.9}
$$

on Riemannian manifolds under an additional condition which was introduced in [\[10\]](#page--1-14)

$$
T_{\lambda} \cap \partial \Gamma^{\sigma} \text{ is a nonempty compact set, } \forall \lambda \in \Gamma \text{ and } \sup_{\partial \Gamma} f < \sigma < f(\lambda), \tag{1.10}
$$

where  $\partial \Gamma^{\sigma} = {\lambda \in \Gamma : f(\lambda) = \sigma}$  is the boundary of  $\Gamma^{\sigma} = {\lambda \in \Gamma : f(\lambda) > \sigma}$  and  $T_{\lambda}$  denote the tangent plane at  $\lambda$  of  $\partial \Gamma^{f(\lambda)}$ , for  $\sigma > \sup_{\partial \Gamma} f$  and  $\lambda \in \Gamma$ . Eq. [\(1.9\)](#page-1-2) in domains of  $\mathbb{R}^n$  was also studied by Ivochkina Download English Version:
