9 Abstract

10 Transrectal palpation of cows is a day-one competence for veterinary students, and it is an essential
11 skill for the diagnosis of pregnancy as well as reproductive disorders. We hypothesized that
12 transrectal palpation induces a stress response in cows, and this stress response may vary with the
13 training students receive before their first transrectal palpation. Therefore, 52 Holstein-Friesian cows
14 were used at the University of Veterinary Medicine Hanover. The experimental group (n = 26) was
15 subjected to transrectal palpations by first and second-year students. Salivary and serum cortisol
16 levels were assessed before and after the intervention. A control group (n = 26) was only restrained
17 and tested for changes in salivary and serum cortisol.

18 A total of 12 cows of the experimental group were examined by two groups of students with
19 different training on two days. The examination was performed one day by students who were
20 theoretically prepared for transrectal palpation in cows (NO-SBT, n = 12). The other day, students
21 who underwent a simulator-based training (SBT, n = 12) performed the examination. The cortisol
22 concentrations, as well as heart rate (HR) and heart rate variability (HRV), were measured in the
23 examined cows. Blood and saliva samples were collected 25 min and immediately before (0 min) and
24 25 min and 85 min after the end of the examination in the experimental group. Serum cortisol levels
25 between 0 min and 25 min were increased by $\Delta 2.6$ ng/ml in the cows in the experimental group
26 compared to $\Delta -0.3$ ng/ml in the control group ($P = 0.001$). The increases in cortisol in saliva ($P =$
27 0.033) and serum ($P = 0.013$) after transrectal palpation were higher in the NO-SBT group $\Delta 0.32$
28 ng/ml saliva, $\Delta 5.8$ ng/ml serum than in the SBT group $\Delta 0.03$ ng/ml saliva, $\Delta 2.1$ ng/ml serum. For HR
29 and HRV analysis values recorded 30 min before the transrectal palpation (-30 min) were set as the
30 baseline concentrations the sequence recorded during the transrectal examination started at 0 min.
31 While the mean HR did not change significantly during the transrectal palpation (80 to 83 bpm SBT
32 students; 81 to 79 bpm NO-SBT students), the HRV parameter square root of the mean squared
