This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

Abstract

Background: Nanofibrillation of proteins by heating at extremely acidic condition for long durations (several hours to days) is studied enthusiastically in food science. The process progresses by the unidirectional self-assembly of peptides as building units of the fibrils.

Scope and approach: This communication provides a review on the underlying mechanism of protein fibrillation, and various technological properties of the fibrils, followed by discussing their biological and cellular effects.

Key findings and conclusions: Fibrillation of proteins and addition of the fibrils into liquid foods causes a significant increase of apparent viscosity. Nevertheless, certain post-fibrillation processes such as freeze-drying may result in viscosity reduction. Fibrils form cohesive viscoelastic interfaces, bringing about high foam and emulsion stability. The presence of non-fibrillated peptides and low molecular weight surfactants influence the foaming and emulsification properties of fibrillated protein solutions. Fibrillated protein can yield cold-set gels at extremely low concentrations, which is attributed to formation of space filling networks. Reinforcing polymeric films, conferring hydrophilic character to graphene, developing drug and nutraceutical delivery vehicles such as microcapsules, microgels and fibrillosome and utilization (mostly as scaffolds) in fabrication of biosensors and bio-sorbents are the other applications of protein fibrils. Fibrillation may increase the antioxidant activity of proteins. It can also influence protein digestibility. Fibrils do not exert any major toxicity towards human cell lines and can be exploited as biomimetic cell culture platforms and cellular transport shuttles.
