ORIGINAL RESEARCH REPORT

# Evaluation of weekly paclitaxel plus carboplatin followed by anthracycline chemotherapy on the neoadjuvant treatment of patients with triple-negative breast cancer

Aurelio B. Castrellon

Medical Oncology-Hematology, Memorial Cancer Institute, Herbert Wertheim College of Medicine, Florida International University, United States

Received 11 January 2017; received in revised form 19 June 2017; accepted 30 July 2017

## KEYWORDS

Triple negative breast cancer;  
Neoadjuvant chemotherapy

## Abstract

**Objective:** To evaluate the effectiveness and tolerability of neoadjuvant chemotherapy with weekly paclitaxel in combination with weekly carboplatin area under curve 2 followed by anthracycline chemotherapy.

**Patients and methods:** This is a retrospective review of electronic medical records of patients ( $N = 32$ ) with stage 1c–III triple-negative breast cancer. Patients received neoadjuvant chemotherapy with paclitaxel 80 mg/m<sup>2</sup> once per week for 12 weeks in combination with carboplatin area under curve 2 once per week for 12 weeks (wP + wCb), followed by a standard anthracycline regimen including either doxorubicin 60 mg/m<sup>2</sup> and cyclophosphamide 600 mg/m<sup>2</sup> every 2 or 3 weeks, or epirubicin 90 mg/m<sup>2</sup> and cyclophosphamide 600 mg/m<sup>2</sup> every 3 weeks for four cycles with myeloid growth factor support.

**Results:** Most patients (91%) received all 12 cycles of wP + wCb, and 88% received all four planned cycles of anthracycline chemotherapy. Of the patients, 84% completed all planned

therapies. The complete pathologic response rate was 60%. In terms of hematologic toxicity, 96% of the patients experienced grade  $\geq 3$  leucopenia, 40% grade  $\geq 3$  anemia, and 15% grade  $\geq 3$  thrombocytopenia, and neutropenic fever was seen in 22% of the patients.

**Conclusion:** The combination of neoadjuvant chemotherapy with wP + wCb before anthracycline chemotherapy can be tolerated by patients with triple-negative breast cancer. Complete pathologic response rates were comparable with those historically seen. Careful selection of patients is fundamental as this regimen is associated with a high incidence of hematologic toxicity.

49 **Introduction**

50 Triple-negative breast cancer (TNBC) accounts for approxi-  
51 mately 20% of breast cancers diagnosed worldwide, repre-  
52 senting almost 200,000 cases each year [1]. The disease  
53 affects more commonly women younger than 40 years of  
54 age [2]. When compared with the other breast cancer sub-  
55 types, patients are also at a higher risk of developing brain  
56 or visceral metastasis [3]. In addition, it appears to be more  
57 common among black women compared with white women  
58 and is associated with the BRCA1 genetic mutation [4].  
59 TNBC is characterized by the absence of expression of the  
60 estrogen receptor, progesterone receptor, and lack of  
61 amplification of the human epidermal growth factor recep-  
62 tor 2 (HER2)/Neu gene [5]. Pathologic complete response  
63 (pCR) rates to neoadjuvant chemotherapy (NACT) among  
64 patients with TNBC range from 27% to 45%, while the pCR  
65 rate for patients with HER2-negative/hormone receptor-  
66 positive breast cancer is generally around 10–20% [6]. How-  
67 ever, while patients with the TNBC who achieve a pCR  
68 appear to have good event-free survival, those with TNBC  
69 who have more than minimal residual disease at surgery  
70 have a much higher risk of early distant disease recurrence  
71 [7,8] Results from previous studies indicate that the addi-  
72 tion of carboplatin (Cb) to standard neoadjuvant anthracy-  
73 cline–taxane chemotherapy results in an increase in pCR  
74 [9,10]. One of the investigational arms of the randomized  
75 phase II Cancer and Leukemia Group B (CALGB40603) clinical  
76 trial tested paclitaxel 80 mg/m<sup>2</sup> once a week (wP) for  
77 12 weeks with concurrent Cb area under curve (AUC) 6 once  
78 every 3 weeks for four cycles, followed by doxorubicin plus  
79 cyclophosphamide once every 2 weeks for four cycles.  
80 Although effective, this regimen has been difficult to repro-  
81 duce in daily practice. The purpose of this study was to eval-  
82 uate the effectiveness and tolerability of weekly paclitaxel  
83 in combination with weekly carboplatin (wP + wCb) AUC 2  
84 followed by anthracycline chemotherapy.

85 **Patients and methods**

86 The electronic medical record system was used to identify  
87 female patients  $\geq 18$  years of age, treated between January  
88 1, 2014 and July 1, 2016, who had operable, biopsy-  
89 confirmed, previously untreated breast cancer with a palpa-  
90 ble size of  $>2$  cm or a sonographical size of  $>1$  cm in maxi-

91 mum diameter, with estrogen receptor and progesterone  
92 receptor expression of 0% and HER2 negativity, defined by  
93 immunohistochemical (IHC) staining 0–1+ or fluorescence  
94 in situ hybridization ratio  $<2.0$  for IHC 2+ or IHC not per-  
95 formed. Adequate hematologic, renal, and hepatic func-  
96 tion, and normal cardiac function by echocardiogram or  
97 radionuclide ventriculogram were required. Patients must  
98 have received NACT with paclitaxel 80 mg/m<sup>2</sup> once per  
99 week for 12 weeks in combination with Cb AUC 2 once per  
100 week for 12 weeks, followed by a standard anthracycline  
101 regimen including either doxorubicin 60 mg/m<sup>2</sup> and  
102 cyclophosphamide 600 mg/m<sup>2</sup> every 2 or 3 weeks, or epiru-  
103 bicin 90 mg/m<sup>2</sup> and cyclophosphamide 600 mg/m<sup>2</sup> every 3  
104 weeks for four cycles with myeloid growth factor support  
105 (granulocyte colony stimulating factor [G-CSF]).

The primary outcome was to evaluate the tolerability of  
106 fractionating Cb to weekly infusions in combination with  
107 weekly paclitaxel. The secondary outcomes included pCR  
108 rate, number of cycles received in each chemotherapy reg-  
109 imen, and frequency of hematologic toxicities.  
110

111 **Pathologic evaluation**

112 Pathologic response was determined locally. The pCR was  
113 defined as the absence of residual invasive disease in the  
114 breast or sampled axillary lymph nodes (ypT0/is ypN0) and  
115 an MD Anderson residual cancer burden index score of zero  
116 (RCB 0).

**Table 1** Stage, BRCA status and KI 67.

	% of patients
KI 67 > 75%	62
KI 67 50–75%	25
KI 67 < 50 %	3
N A	9
Stage I	6
Stage II	53
Stage III	41
BRCA 1/2	12
