**ABSTRACT:** Water temperature fluctuations are considered to be a major factor affecting the immune functions and metabolic processes of scallops. To better understand the immune defense mechanisms of Yesso scallop, *Patinopecten yessoensis* following exposure to water temperature fluctuations, transcriptomic profiles in the gills from high-frequency fluctuations (HF\_G), low-frequency fluctuations (LF\_G), and no fluctuations (NF\_G) groups were obtained using HiSeq™ 2500 (Illumina). For HF\_G, scallops were transferred directly between 18 and 8°C every 4 h and for 10 fluctuations, while scallops in LF\_G were transferred between 18 and 13°C every 12 h, for a total of 4 fluctuations. A total of 442,922,590 clean reads were generated in 9 libraries and then assembled into 210,780 unigenes with an average length of 705 bp and an N50 of 1253 bp. Based on sequence similarity, 54,529 unigenes (25.87%) were annotated in at least one database. Comparative analysis revealed that 696 unigenes differentially expressed in temperature stressed groups compared with the control, including 229 unigenes between HF\_G and NF\_G, and 548 unigenes between LF\_G and NF\_G, respectively. Additionally, among these differentially expressed genes (DEGs), there were 41 immune-related unigenes and 16 protein metabolism-related unigenes. These results provide fundamental information on the molecular defense mechanisms in the Yesso scallop gills after exposure to water temperature fluctuations.

**Key words:** Transcriptome, *Patinopecten yessoensis*, water temperature fluctuations

## 1. Introduction
