### ABSTRACT

The mitochondrial genome (mitogenome) provides important information for phylogenetic analysis and understanding evolutionary origins. Herein, we sequenced, annotated, and characterised the mitogenome of the crab *Helice wuana* to better understand its molecular evolution and phylogeny. The 16,359 bp mitogenome includes 13 protein-coding genes (PCGs), 22 transfer RNA (tRNA) genes, two ribosomal RNA (rRNA) genes and one control region. The genome composition is highly A + T biased 68.42%, and exhibits a negative AT-skew ( $-0.036$ ) and GC-skew ( $-0.269$ ) among Brachyura crabs. Gene rearrangements were detected, as was tandem duplication followed by random loss, which explains the translocation of mitochondrial genes. Phylogenetic analysis showed that *H. wuana* and *H. tientsinensis* clustered on one branch with high nodal support values. These results confirm that the placement of *H. wuana* within the Varunidae family of Thoracotrematan crabs. This study will provide a better understanding for gene rearrangements and crab evolution in the future.

### 1. Introduction

Decapoda is an economically important order of crustaceans comprising 18,000 living and extinct species [1], such as freshwater crayfish, lobsters, hermit crabs, shrimps, and ‘true’ crab [2]. Decapoda is the most species-rich, abundant, visible, popular, and economically important order of crustaceans, supporting seafood and marine industries worth billions of dollars each year to the world economy. Traditionally, Decapoda are divided into Dendrobranchiata and Pleocyemata sub-orders, and the Brachyura infra-order, belonging to Pleocyemata, is among the most diverse group, with over 7000 described species in 98 families inhabiting marine, freshwater, and terrestrial habitats [3–6]. Brachyura, the true crabs, is the largest clade Decapod Crustacea [7,8]. Due to the extreme morphological and ecological diversity, phylogenetic relationships within Brachyura are complicated [9]. The Grapsoidea crab, belonging to the higher taxa in the classification system, appeared late in the evolution of crustaceans, multiplied in the Tertiary period of the Cenozoic era, and gradually became dominant. *Helice wuana* is a mudflat crab inhabiting Chinese coastal regions including Guangdong, Fujian, Jiangsu, and Shandong peninsulas, and the Gulf of Bohai and Liaotung [2,10]. It is also common in North Korea and Japan. *H. wuana* burrows in intertidal mudflats, swamps, salt marshes and

estuaries, especially in the high intertidal and supralittoral zones [10,11]. It is semi-terrestrial, returning to sea to spawn [12]. *H. wuana* also has a salinity requirement which lies between those of two other estuarine crabs in Japan, *Helicana japonica* and *Chiramantes dehaani* [13]. *H. wuana* is one of the most economically important crustacean species in aquaculture in China.

In metazoans, the mitochondrial genome (mitogenome) is usually small (~14–16 kb) and contains 13 protein-coding genes (PCGs), 22 transfer RNA genes (tRNAs), two ribosomal RNA genes (*rns* and *rnl*) and a control region [14]. In animals, the mitochondrial control region is the only non-coding sequence in the mitogenome, and it is called D-loop region in vertebrates and the A + T-rich region in invertebrate [15,16]. The control region contains initiation sites for transcription and replication. With the development of sequencing technologies, complete mitogenomes can now be rapidly sequenced to investigate phylogenetic matters. Besides being used for reconstruction of phylogenetic relationships, complete mitogenomes can also provide information on gene rearrangements and nucleotide bias [17]. Mitogenome sequences are now widely used in population genetics, comparative and evolutionary genomics, reconstruction of phylogenetic relationships, and molecular evolutionary research [18–21]. Numerous analyses of Decapoda have been published based on molecular from the
