This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

Highlights:

- Here we propose a hypothesis of multiple sclerosis aetiology
- First, a sequential double hit of *Enterobius Vermicularis* and Epstein-Barr Virus
- This might explain some of the unusual epidemiology of the condition
- If correct, EBV might directly establish latency in mature memory B-Cells
- The final mechanism would be specific T-Cell exhaustion for a viral protein (LMP2A)
