Abstract

We report a case of severe infection with liver abscess and endophthalmitis caused by a hypervirulent *Klebsiella pneumoniae* strain in an immunocompetent German male patient without travel history to Asia. Phenotypic and molecular characterization showed high similarity to the reference genome NTUH-K2044 isolated in Asia. The isolate was assigned as ST2398 (clonal complex 66). The findings underline global spread of hypervirulent *Klebsiella pneumoniae* strains to Europe.

Introduction

Klebsiella pneumoniae is one of the organisms that merits particular attention as a result of rising resistance problems causing high numbers of both healthcare- and community-acquired infections, mainly urinary tract, respiratory tract or bloodstream infections [1]. Apart from antimicrobial resistance—mainly due to β -lactamases like extended-spectrum β -lactamases (ESBL), AmpC β -lactamases or carbapenemases—so-called hypervirulent strains have emerged primarily in Asia, but recent data suggest a worldwide spread [2,3]. Antimicrobial resistance and hypervirulence are mostly not overlapping [4]. Nonetheless, cases due to hypervirulent carbapenem-resistant *K. pneumoniae* have been described, particularly in Taiwan and China [5,6].

To date, there is no consistent definition of hypervirulence in literature. Hypervirulent *K. pneumoniae* strains typically have a hypermucoviscous phenotype and belong to serotype K1 or K2 [7]. Two genes have previously been associated with invasive infections, the mucoviscosity-associated gene A (*magA*) and the regulator of mucoid phenotype A (*rmpA*) [8]. *magA* is located in the same gene cluster specifying serotype K1 and encodes a particular capsular polymerase. In accordance with the bacterial polysaccharide gene nomenclature (BPGN) scheme, it was suggested to be renamed *wzy(KpK1)* [9]. The *rmpA* gene is a plasmid-borne regulator of extracellular polysaccharide synthesis. Hypervirulent strains possess various iron acquisition systems, including enterobactin (Ent); the prototypical catecholate siderophore aerobactin, a hydroxamate siderophore whose receptor is encoded by *iutA*; and yersiniabactin (*ybtS*), a phenolate-type siderophore that is structurally distinct from Ent [10]. *Kfu*, which mediates uptake of ferric iron, seems to be present in many hypervirulent strains [11]. Liver abscess has been associated with demonstration of *allS*, a gene relevant in allantoin metabolism [12]. Other genes found include fimbrial and nonfimbrial adhesion genes, such as *ycfM*, *KPN* and *mrkD*. The latter is believed to function as the type 3 fimbrial adhesin and to mediate binding to the extracellular matrix [13].

A 61-year-old previously healthy man presented with fever for 3 days, progressive jaundice and a red left eye with pain and lid swelling, as well as reduced vision in his left eye. He denied any travel to Asia but reported a recent journey to Brazil. He was hospitalized with the presumptive diagnosis of an endophthalmitis as a consequence of systemic infection. At admission his vital signs included a body temperature of 38.7°C, heart rate of 140 beats per minute and an elevated blood

pressure of 170/100 mm Hg. Scleras and skin were icteric; no rash was observed. No tenderness could be elicited in any quadrant of the abdomen; hepatosplenomegaly was not detected. Neurologic examination was revealed nothing abnormal. The initial laboratory examination revealed mild leucocytosis (white blood cell count 13 800/mL) and thrombocytopenia (platelet count 123 000/mL). Levels of C-reactive protein (CRP) and liver enzymes were markedly elevated (CRP 252 mg/L, alanine aminotransferase 59 U/L, alkaline phosphatase 156 U/L, total bilirubin 5.7 mg/dL). Kidney function was preserved. Clotting factors were in the normal range. Computed tomographic scan revealed a liver abscess in segment II (4.8 × 4.2 cm). Obstructive cholestasis or any other intrabdominal pathology was not present. The patient underwent emergent ultrasound-guided percutaneous catheter drainage of the liver abscess. Intravenous piperacillin/tazobactam 4.5 g three times daily was empirically administered, and intravenous levofloxacin 750 mg once daily was added 3 days later. Cultures from the liver abscess yielded *K. pneumoniae*. Blood cultures taken at admission remained sterile. To clarify the extent of the disease, a head magnetic resonance imaging (MRI) was done, which permitted us to exclude a brain abscess. Transthoracic echocardiography revealed no signs of endocarditis. Furthermore, the patient underwent colonoscopy to rule out a diverticulitis or colorectal carcinoma as the underlying focus. Cultures from vitreous samples remained negative in culture but were PCR positive. Follow-up MRI of the abdomen 6 days later showed a reduction in abscess cavity size but unfortunately revealed a thrombosis of adjacent left hepatic vein as well as a new abscess cavity located dorsally to the original abscess. The new abscess was interpreted as a complication of the percutaneous abscess drainage. A repeated percutaneous drainage or surgical intervention was not indicated. The patient was successfully treated by intravenous antibiotic therapy with piperacillin/tazobactam for 10 days followed by oral levofloxacin for up to 4 weeks. Repeated abdominal ultrasound during follow-up revealed complete resolution of the liver abscess.

Materials and Methods

Susceptibility testing

Minimum inhibitory concentrations (MICs) for various antibiotics were obtained by broth microdilution antimicrobial susceptibility testing with the Micronaut system (Merlin Diagnostika, Bornheim-Hersel, Germany) according to standard procedures ISO 20776-1:2006. Results were interpreted according to European Committee on Antimicrobial Susceptibility Testing (EUCAST) breakpoints (Breakpoint tables for

interpretation of MICs and zone diameters, version 6.0, 2016, <http://www.eucast.org>). MIC values of relevant β-lactam agents are shown in Table 1. Phenotypic detection of ESBL production could be excluded with the combination disc test as recommended by EUCAST using cefotaxime, ceftazidime and cefepime with or without clavulanate. AmpC production was excluded by cefoxitin/cloxacillin disc test.

Determination of virulence factors

The isolate underwent further phenotypic and molecular tests for a series of virulence factors. Hypermucoviscosity was defined by a positive string test, which monitored the formation of a viscous string that is greater than 5 mm in length by stretching bacterial colonies on an agar plate as previously described [14]. DNA was extracted from pure cultures with the Ultraclean Microbial DNA isolation kit (Mo Bio Laboratories, Carlsbad, CA, USA). The DNA library was prepared using the Nextera XT library preparation kit with the Nextera XT index kit (Illumina, San Diego, CA, USA). Subsequently, the library was sequenced on a MiSeq sequencer using the MiSeq reagent kit generating 250 bp paired-end reads (Illumina, San Diego, CA, USA) aiming at a coverage of at least 60-fold. Quality trimming of reads was performed with CLC Genomics Workbench 9.0.1 (Qiagen, Hilden, Germany) using a minimum Phred (Q) score of 28. *De novo* assembly was performed using CLC Genomics Workbench 7.0.4 (Qiagen) with optimal word sizes based on the maximum N50

TABLE 1. Summary of relevant characteristics of K2 *Klebsiella pneumoniae* isolate KP_FR_2016 sequence type 2398 (clonal complex 66)

Characteristic	Value
MICs for selected β-lactams determined by broth microdilution (Micronaut system) (mg/L)	
Ampicillin/sulbactam	2
Amoxicillin/clavulanate	4
Piperacillin/tazobactam	1
Ceftazidime	0.25
Cefotaxime	0.25
Cefepime	0.25
Meropenem	0.5
Ertapenem	0.125
Levofloxacin	0.06
Resistance profile	Negative for ESBL, AmpC, carbapenemase
Virulence-associated features	
Hypermucoviscosity (defined by positive string test) [14]	Positive
<i>Cps</i> genotype	K2
Virulence gene profiles	
<i>magA</i> gene	Not detected
<i>rmpA</i> gene	Present
Iron acquisition	
Aerobactin (<i>iutA</i> gene)	Present
<i>kfu</i> gene	Not detected
<i>entB</i> gene	Present
<i>ybtS</i> gene	Present
Allantoin metabolism	
<i>allS</i> gene	Not detected
Adhesins	
<i>mrkD</i> gene	Present

ESBL, extended-spectrum β-lactamase; MIC, minimum inhibitory concentration.
