This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

Highlights

- Depressed patients were randomized to receive one week of escitalopram or placebo
- fMRI revealed attenuated self-referential processing in the escitalopram group
- Escitalopram increased responses to positive self-processing in the MPFC/ACC
- There was yet no mood improvement, suggesting a direct effect of escitalopram
- This early change may have a role in antidepressants' mechanism of action
