This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

Highlights

- In kin selection theory in the evolution of social behaviors, the relatedness between players is influenced by the spatial structure of the population.
- Generally, it has been pointed out that 'viscosity' of population is unlikely to promote altruism evolution. We consider that more complex interactions produce specific spatial patterns, which could alter a process of kin selection on the space.
- Thus, we theoretically studied the joint evolution of altruism and resource exploitation in a spatially structured population.
- The analysis indicates that the joint evolution can form regularly-arranged cluster structures, which creates a new 'level of selection', and significantly promotes the altruism evolution.
- Our analysis also suggests an important relationship between niche theory and multilevel selection, two important concepts in ecology and evolutionary biology.
