This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

ACCEPTED MANUSCRIPT

Highlights

- This paper presents a simple mathematical model of how cells (and small clusters of cells) can combine to form large clusters due to chemotaxis.
- An exact expression is used to simulate how the chemical signals produced by the cells diffuses and spreads out.
- The effect that changing some of the parameters in the model, such as the initial concentration strength and the diffusion constant, has on the final distribution of the cells is investigated and discussed.
